ILLUSTRATED JOURNAL OF SCIENCE

VOLUME CV

MARCH, 1920, to AUGUST, 1920

To the solid ground
"Of Nature trusts the mind which builds for aye."—WORDSWORTH

London
MACMILLAN AND CO., LIMITED
NEW YORK: THE MACMILLAN COMPANY

[*Nature*,
October 7, 1920

PRINTED IN GREAT BRITAIN BY
RICHARD CLAY AND SONS, LIMITED,
BRUNSWICK STREET, STAMFORD STREET, S.E. 1,
AND BUNGAY, SUFFOLK.

INDEX.

NAME INDEX.

Abbot (Dr. C. G.), A New Method of Determining the Solar Constant of Radiation, 667; Solar Variation and the Weather, 678
Abel (Prof. J. J.), The Honorary Degree of Doctor of Law conferred upon, by Cambridge University, 730
Abelous (J. E.), and J. Aloy, Digestive Hydrolyses by Mechanical Ionisation of Water, 380
Ackermann (A. S. E.), British and Metric Systems of Weights and Measures, 456; Curious Formation of Ice, 741; and others, Grants from the Dixon Fund of the University of London, 569
Acland (F. D.), and H. A. L. Fisher, The Directorship of Research to the Glass Research Association, 178
Adami (Dr. T. G.), elected an Honorary Fellow of Christ's College, Cambridge, 440; elected an Honorary Fellow of Jesus College, Cambridge, 505
Adams (Prof. E. P.), The Einstein Theory, 842
Adams (F. D.), elected a Foreign Associate of the U.S. National Academy of Sciences, 463
Adeney (Prof. W. E.), and H. G. Becker, The Rate of Solution of Atmospheric Nitrogen and Oxygen by Water (Part iii.), 379
Adkin (R.), Migrations of Butterflies and Moths in regard to the British Islands, 530
Adlam (C. H. J.), Acids, Alkalis, and Salts, 705
Adrian (Dr.), appointed University Lecturer in Physiology in Cambridge University, 537
Agar (Prof. W. E.), Cytology: with special reference to the Metazoan Nucleus, 482
Agnew (A. P.), The "Ilford Tropical Hardener," 182
d'Albe (Dr. E. E. Fournier), The Optophone: An Instrument for Reading by Ear, 205
Alexander (Dr. C. P.), An Undescribed Species of Clytocosmus, Skuse (Tipulidæ, Diptera), 635
Alexander (Prof. S.), Space, Time, and Deity: The Gifford Lectures at Glasgow, 1916–18, 2 vols., 798
Allbutt (Sir T. Clifford), Portrait of, by Sir William Orpen, in the Royal Academy, 335; to be Sworn a Member of the Privy Council, 500; Presidential Address to the British Medical Association, 661
Allcock (H.), Decimal Coinage, 261
Allen (Sir Charles), [obituary], 239
Allen (Dr. E. J.), and E. W. Sexton, Mutations in Eye-colour in *Gammarus chevreuxi*, 368
Allen (Dr. H. S.), An Electronic Theory of Isomerism, 71
Allioft (E. A.), Recessed Plate and Plate-and-Frame Types of Filter Press, 696
Allmand (Prof. A. J.), Anti-Gas Fans, 453, 612
Amar (J.), Attitudes of the Body and Respiration, 635; The Index of Respiratory Endurance, 59
Ameghino (Dr. C.), appointed Director of the National Museum of Natural History, Buenos Aires, 80; Discovery of Ancient Human Remains in Buenos Aires, 209
Amos (A.), appointed University Lecturer in Agriculture in Cambridge University, 88
Ampferer (Dr. O.), Influence of Deep Notches cut by Erosion on Tectonic Features, 836
Amundsen (Capt. R.), News of the Expedition of, 240, 273, 305
Anderson (J.), appointed Lecturer in Logic and Metaphysics in the University of Edinburgh, 280
Anderson (J. A.), Spectra of Explosions, 668
Anderson (J. Wemyss), appointed Professor of Engineering Refrigeration in Liverpool University, 376
Andrew (Dr. J. H.), appointed Professor of Metallurgy in the Royal Technical College, Glasgow, 249
Andrewes (Sir Frederick), to Deliver the Harveian Oration, 722
Andrews (E. S.), Elements of Graphic Dynamics, 65
Angell (Dr. J. R.), elected President of the Carnegie Corporation of New York, 527; Relation of Psychology to the National Research Council, 796
Angles (J. W.), Mensuration for Marine and Mechanical Engineers (Second and First Class Board of Trade Examinations), 163
Annandale (Dr. N.), and others, Biological Papers from Bengal, 436
Anthony (H. E.), Mammalian Remains in Jamaica, 757
Appleton (E. V.), appointed an Assistant Demonstrator in Experimental Physics in the University of Cambridge, 56
Arber (Dr. Agnes), awarded a Keddey Fletcher-Warr Studentship by the University of London, 155; The Binucleate Phase in the Plant-cell, 90
Ariès (E.), The Equation of State of Ether, 314
Armstrong (E. C. R.), Ancient Gold Articles found in an Irish Bog, 527
Armstrong (Dr. E. F.), Catalytic Chemical Reactions and the Law of Mass Action, 696; and T. P. Hilditch, A Study of the Catalytic Action at Solid Surfaces, iii. and iv., 314; v., 631
Armstrong (Prof. H. E.), A Chemical Service for India, 669
Arthur (Sir George), Life of Lord Kitchener, 3 vols., 319
Ascoli (M.), and A. Fagiuoli, Sub-epidermic Pharmacodynamic Experiences, ii., iii., 844
Ashfield (H. W.), Scientific Apparatus and Laboratory Fittings, 357
Ashworth (Dr. J. R.), A Possible Cause for the Diamagnetism of Bohr's Paramagnetic Hydrogen Atom, 516; The Diamagnetism of Hydrogen, 645
Asiatic Petroleum Company, Gift to Birmingham University, 154
Aston (Dr. F. W.), elected to a Fellowship in Trinity College, Cambridge, 568; Isotopes and Atomic Weights, 617; The Constitution of the Elements, 8, 547; The Separation of the Element Chlorine into Normal Chlorine and Meta-Chlorine, and the Positive Electron, 231; and T. Kikuchi, Moving Striations in Neon and Helium, 633
Atack (F. W.), assisted by L. Whinyates, The Chemists' Year Book, 1920, 2 vols., 740
Atanasoff (D.), and A. G. Johnson, The Use of Dry Heat for the Disinfection of Cereal Seeds, 310
Athanasiu (J.), The Supposed Dynamogenic Power of Alcohol, 251
Atwood (Dr. W. W.), appointed President of Clark University and College, 602
Audant (M.), The Critical State of Ethyl Ether, 634

Auger (V.), The Salts of Nitrosophenylhydroxylamine (Cupferron): Uranous Salts, 379
Ault (Capt. J. P.), Results of the Magnetic Survey of the Atlantic made by the *Carnegie*, 529; Results of the Magnetic Observations taken by the *Carnegie* in February and March, 1920, 788
Austen (Major), The House-fly, 787
Austin (Major E. E.), awarded a Mary Kingsley Medal, 697
Avery (Margaret), A Text-book of Hygiene for Training Colleges, 259
Ayrton (Mrs. Hertha), Anti-Gas Fans, 336, 422, 612, 613

B. (A.), A Note on Telephotography, 488
Backhouse (T. W.), [obituary], 335; Bequests by, 630
Bacon (Mrs. P.), Bequest to the U.S. National Museum, 628
Baglioni (Sig.), Life and Work of the late Prof. L. Luciani, 844
Bagshawe (Dr. A. G.), awarded a Mary Kingsley Medal, 696
Bailey (Prof. L. H.), reorganising the American Pomological Society, 623
Bainbridge (Mr.), The Solubility of Basic Slag in Citric and Carbonic Acids, 184
Baird (D. W.), British and Foreign Scientific Apparatus, 390; History of the Formation of the British Lamp-blown Scientific Glassware Manufacturers' Association, Ltd., 496
Bairstow (L.), Applied Aerodynamics, 95; Knowledge and Power, 135
Baker (C.), Scientific Apparatus and Laboratory Fittings, 356
Baker (F. C.), Mollusca obtained by the Crocker Land Expedition, 593
Baker (F. W. Watson), British and Foreign Scientific Apparatus, 518
Baker (Prof. H. F.), Construction of the Ninth Intersection of Two Cubic Curves passing through Eight given Coplanar Points, 474
Baker (Julian), re-elected Chairman of the London Section of the Society of Chemical Industry, 526
Baker (Prof. R. P.), Engineering Education: Essays for English, selected and edited by, 258
Baker (R. T.), The Hardwoods of Australia and their Economics, 802
Baker (Commander T. Y.), A New Method for Approximate Evaluation of Definite Integrals between Finite Limits, 486
Baldet (F.), The Diurnal Variation of the Atmospheric Potential at the Algiers Observatory, 283
Balfour (Dr. A.), awarded a Mary Kingsley Medal, 697
Balfour (H.), Presidential Address to the Somersetshire Archæological and Natural History Society, 835
Ball (Dr. J.), Astrolabe Diagram, 329; Use of Sumner Lines in Navigation, 806; and H. Knox Shaw, A Handbook of the Prismatic Astrolabe, 329
Ballantyne (Dr. A. J.), appointed Lecturer in Ophthalmology in Glasgow University, 761
Ballou (H. H.), Cotton Pests, 503; and others, The Resistance of Plants to Insect Attacks, 503
Balls (Dr. W. Lawrence), Cotton-growing in the British Empire, 103; Researches on Egyptian Cotton, 664; The Nature, Scope, and Difficulties of Research, 497; Trichodynamics, 777
Balsillie (D.), The Intrusive Rocks of the Dundee District, 666
Banks (Sir Joseph), The Centenary of, 530
Bannister (C. O.), appointed Professor of Metallurgy in Liverpool University, 630
Barber (Dr. C. A.), appointed Lecturer in Tropical Agriculture in the University of Cambridge, 537
Barcroft (J.), Presidential Address to Section I of the British Association, 828
Barjon (F.), Translated by Dr. J. A. Honeij, Radio-Diagnosis of Pleuro-Pulmonary Affections, 4
Barker (Prof. A. F.), A Summer Tour (1919) through the Textile Districts of Canada and the United States, 789
Barker (E.), appointed Principal of King's College, London, 630
Barling (Sir Gilbert), The Need for Increasing the Stipends in Birmingham University, 730
Barlot (J.), Determination of Poisonous Varieties of Amanita by Colour Reactions, 219
Barlow (W.), Models illustrating the Atomic Arrangement in Potassium Chloride, etc., 570
Barnard (Prof.), Photographs of the Brorsen-Metcalf Comet, 467
Barratt (S.), The Origin of the "Cyanogen" Bands, 63[illegible]
Bartholomew (Dr. J. G.), [obituary article], 238; Bequest to the University of Edinburgh, 537
Bartlett (Capt. F. W.), and Prof. T. W. Johnson, Engineering Descriptive Geometry and Drawing. 3 parts, 515
Bartrum (C. O.), A Rainbow Inside Out, 388
Bartsch (P.), Experiments in the Breeding of Cerions, 545
Barus (Prof. C.), An Example of Torsional Viscous Retrogression, 667; Displacement Interferometry by the aid of the Achromatic Fringes. Part iv., 563
Bary (P.), The Viscosity of Colloidal Solutions, 539
Bateson (Dr. W.), Prof. L. Doncaster, 461; Genetic Segregation, 531; Organisation of Scientific Work, 6
Bather (Dr. F. A.), Museums and the State, 69; Presidential Address to Section C of the British Association, 826
Battestini (M.), The Optimum Magnification of a Telescope, 443
Bauer (Dr. L. A.), Magnetic and Electrical Observations and their Reduction, 20; Results of Geophysical Observations during the Solar Eclipse of May 29, 1919, and their Bearing upon the Einstein Deflection of Light, 842; The Solar Eclipse of May, 1919, 311
Bayliss (Prof. W. M.), British and Foreign Scientific Apparatus, 641; Scientific Apparatus from Abroad, 293; The Circulating Blood in Relation to Wound Shock, 10; The Properties of Colloidal Systems, iv.: Reversible Gelation in Living Protoplasm, 26; The Rockefeller Gift to Medical Science, 501
Beamish (A. J.), elected to the Wrenbury Scholarship in Economics in Cambridge University, 601
Beccari (Dr. O.), The Palms of the Philippines, 180
Beck (C.) Scientific Apparatus and Laboratory Fittings, 355
Becker (Prof. L.), Capture Orbits, 560; The Daily Temperature Curve, 282
Beddard (Dr. F. E.), Two Embryos of the Sperm Whale, 275
Bedford (the Duke of), The Cancer Research Fund, 696
Beer (R.), and Dr. Agnes Arber, Multinucleate Cells, 90
Beeson (C. F. C.), The Toon Shoot and Fruit Borer, 629
Bell (A. J. M.), [obituary], 721
Bellingham and Stanley, Ltd., Scientific Apparatus and Laboratory Fittings, 357
Belot (E.), L'Origine des Formes de la Terre et des Planètes, 559
Bemmelen (Dr. W. van), High Rates of Ascent of Pilot Balloons, 485
Benedicks (Prof. C. A. F.), Recent Progress in Thermo-Electricity, 499
Benedict (F. G.), The Basal Metabolism of Boys from One to Thirteen Years of Age, 667
Bennett (A. G.), The Occurrence of Diatoms on the Skin of Whales, 633
Bennett (G. T.), The Rotation of a Non-spinning Gyrostat, and its Effect in the Aeroplane Compass, 378
Benson (O. H.), and G. H. Betts, Agriculture and the Farming Business, 35
Berger (E.), Some Reactions Started by a Primer, 603
Bernewitz (Dr.), The Duplicity of ν Geminorum, 340
Berry (A. J.), re-elected to a Fellowship at Cambridge University, 761
Berthoud (Prof. A.), The Structure of Atoms, 306
Bertrand (G.), Action of Chloropicrin upon the Higher Plants, 283; Conditions which may Modify the Activity of Chloropicrin towards the Higher Plants, 347; and M. Brocq-Rousseu, The Destruction of Rats by Chloropicrin, 27; and Mme. Rosenblatt, Action of Chloropicrin upon some Bacterial Fermentations, 571; Action of Chloropicrin upon Yeast and *Saccharomyces vini*, 507; Does Chloropicrin Act upon Soluble Ferments?, 699

Barwick (W. E. H.), appointed Lecturer in Mathematics in the University of Leeds, 564; Quintic Transformations and Singular Invariants, 474
Besson (L.), The Actinometers of Arago and Bellani, 283
Betts (Annie D.), Daylight Saving and the Length of the Working Day, 41
Bevan (W.), The Agricultural Industries of Cyprus, 757
Beveridge (Sir William), A Hitherto Unrecognised Periodicity in the Weather and the Crops, 370
Bianco (O. Z.), "La Trepidazione in Dante?" 664
Bidder (Dr. G. P.), Sponges, 441
Bigourdan (G.), The Instruments and Work of the Sainte-Geneviève Observatory, 475
Birchenough (Sir Henry), appointed Chairman of the British Dyes Corporation, 303; Importance of the Dye Industry, 413
Birkett (M. S.), The Iron and Steel Trades during the War, 787
Bishop (F. C.), and H. P. Wood, A Remedy against Lice in Poultry, 663
Bispham (Capt. J. W.), An Experimental Determination of the Distribution of the Partial Correlation Coefficient in Samples of 30, 187
Bjerknes (Prof. V.), The Meteorology of the Temperate Zone and the General Atmospheric Circulation, 522
Blacklock and Carter, *Anopheles plumbeus*, 241
Blackman (Dr. A. M.), "The House of the Morning" in Egyptian Ritual, 241
Blackman (Dr. F. F.), The Protoplasmic Factor in Photosynthesis, 89
Blair (Sir Robert), Presidential Address to Section L of the British Association, 828
Blaise (E. E.), The Action of Hydrazine on the 1 : 4 Acyclic Diketones, 506; The Action of Substituted Hydrazines upon Acyclic 1 : 4-Diketones, 666
Blake (E.), Selected Studies in Elementary Physics: A Handbook for the Wireless Student and Amateur, 739
Blake (Dr. F. G.), The Relation of the *Bacillus influenzae* to Influenza, 763
Blakeslee (E. B.), The Control of the Peach-borer, 629
Blamires (Mrs. M.), Gift to the Huddersfield Technical College, 185
Blaringham (L.), The Stability and Fertility of the Hybrid *Geum urbanum* × *G. rivale*, 475
Bloch (L. and E.), Production of the Band Spectra of Nitrogen by Electrons of Low Velocity, 539; Some new Spark Spectra in the Extreme Ultra-violet, 27
Blythe (E.), A Text-book on Machine Drawing for Electrical Engineers, 260
Boerker (Dr. R. H. D.), Our National Forests: A Short Popular Account of the Work of the U.S. Forest Service on the National Forests, 577
Boirac (E.), The Psychology of the Future ("L'Avenir des Sciences Psychiques"), Translated and Edited with an Introduction by W. de Kerlor, 323
Bond (Hon. Col. C. J.), Loss of Fragrance of Musk Plants, 709
Bone (Prof. W. A.), The Position of University Teachers in relation to the Teachers (Superannuation) Act, 89
Bonney (Prof. T. G.), Marlborough R. Pryor, 333
Bonnier (Prof. G.), elected a Foreign Member of the Linnean Society, 366; The Changes in Plant Forms Obtained Experimentally, 539
Boot (Sir Jesse), Gift to University College, Nottingham, 665
Borchardt (W. G.), School Mechanics. Part i., School Statics, 163
Borradaile (L. A.), A Manual of Elementary Zoology. Third edition, 804
Bose (Sir Jagadis Chandra), Conferment upon, of an Honorary Degree by Aberdeen University, 154; Experiments on Movements in Plants, 305; Life Movements in Plants, 436; Organisation of Scientific Work, 39; Researches on Growth of Plants, 615, 648
Bosworth (Dr. T. O.), Geology of the Mid-Continent Oilfields. Kansas, Oklahoma, and North Texas, 608
Bottazzi (F.), Researches on the Posterior Salivary Gland of Cephalopodes (iii.), 251
Bougault (J.) and J. Perrier, New Researches Relating to the Action of Hydrocyanic Acid on Glucose, 539; The Action of Hydrocyanic Acid on Glucose; Kiliani's Reaction, 443; and P. Robin, The Iodoamidines, 666
Boulin (Ch.), and L. J. Simon, Action of Water on Dichloroethyl Sulphide, 283; The Preparation of Methyl Chloride and Bromide starting from Dimethyl Sulphate, 218
Bourion (F.), A Method of Physico-chemical Analysis of Commercial Chlorobenzenes, 379; Kinetic Study of the Chlorination of Benzene, 506; The Analysis of Commercial Chlorobenzenes by Distillation, 347; The Impurities of the Benzene extracted from Commercial Chlorobenzenes, 443
Bourquelot (Em.), and M. Bridel, A New Glucoside capable of Hydrolysis by Emulsin, Scabiosine, 187; Detection and Characterisation of Glucose in Plants by a New Biochemical Method, 218; The Biochemical Preparation of Cane-sugar starting with Gentianose, 666; and H. Hérissey, The Presence in the Melilot and Woodruff of Glucosides furnishing Coumarin under the Hydrolysing Action of Emulsin, 634
Boutroux (Prof. P.), Les Principes de l'Analyse Mathématique: Exposé Historique et Critique. Tome ii., 256
Bower (Prof. F. O.), The Earliest Known Land Flora, 681, 712
Bowie (W.), Report on the Connection of the Arcs of Primary Triangulation along the Ninety-eighth Meridian in the United States and in Mexico, and on Triangulation in Southern Texas, 141
Bowlby (Sir Anthony A.), elected President of the Royal College of Surgeons of England, 622
Boys (Prof. C. V.), A Noon Reflector, 117
Braak (Dr. C.), Atmospheric Variations of Short and Long Duration in the Malay Archipelago and Neighbouring Regions, and the Possibility to Forecast Them, 729
Brabrook (Sir Edward), Anthropology and Economics during the Past Quarter of a Century, 530; Sir Norman Lockyer, 784
Bradford (S. C.), An Electronic Theory of Isomerism, 171; Langmuir's Theory of Atoms, 41, 725
Bradley (Dr. O. C.), elected President of the Royal (Dick) Veterinary College, Edinburgh, 601
Bragg (Sir W. H.), elected an Honorary Fellow of Trinity College, Cambridge, 88; Increased Interest in Scientific Studies, 281; to receive the Honorary Degree of D.Sc. from the University of Dublin, 89
Bragg (Prof. W. L.), Crystal Structure, 646
Braly (Ad.), Method for Collecting and Characterising the Sublimates Produced by Metalloids and Metals Volatilised by the Blowpipe, 219
Brashear (Dr. J. A.), [obituary], 273
Brenchley (Dr. W. E.), Sugar Cultivation in India, 840; The Improvement of Grassland, 408
Breuil (l'Abbé), appointed Munro Lecturer for 1920-21 in Edinburgh University, 121
Bridgman (Dr. P. W.), Effects of Pressure on the Electrical Resistance and Thermo-electric Properties of Metals, 529
Brierley (Mrs. S.), The Present Attitude of Employees to Industrial Psychology, 400
Brierley (W. B.), A Form of *Botrytis cinerea* with Colourless Sclerotia, 186; Ellis's Applied Botany, 164
Briggs (G. E.), elected to the Allen Scholarship in Cambridge University, 154; The Beginning of Photosynthesis in the Green Leaf, 89
Brindley (H. H.), Further Notes on the Food-plants of the Common Earwig (*Forficula auricularia*), 378
Brindley (H. S. B.), [obituary], 208
British Dyestuffs Corporation, Gift to Oxford University towards the Extension of the Organic Chemical Laboratory, 313
Britten (J.), Banks as a Botanist, 530
Britton (N. L.), and C. P. Berkey, The Scientific Survey of Porto Rico and the Virgin Islands, 147
Brives (A.), Some Results of a New Journey in Morocco, 475
Broad (Dr. C. D.), appointed Professor of Philosophy in Bristol University, 630

Broden (Dr. A. L. G.), awarded a Mary Kingsley Medal, 697
Brodetsky (Dr. S.), A Graphical Treatment of Differential Equations, 466; Mathematics: Pure and Applied, 65
Brodie (J. A.), elected President of the Institution of Civil Engineers, 304
Broglie (L. de), Calculation of the Limiting Frequencies of K and L Absorption of the Heavy Elements, 218; The Fine Structure of X-ray Spectra, 475
Brook (A.), The Buzzard at Home, 746
Brooks (C. E. P.), Climates of the British Empire Suitable for the Cultivation of Cotton, 338; The Climate and Weather of the Falkland Islands and South Georgia, 275
Brooks (F. S.), The Control of the Apple-tree Borer, 629
Brotherus (Prof. V. F.), elected a Foreign Member of the Linnean Society, 366
Brown (Prof. Adrian), Erection of a Memorial Tablet to, in the Brewing School of Birmingham University, 154
Brown (G. E.), The British Journal Photographic Almanac and Photographer's Daily Companion, 1920, 66
Brown (O. F.), appointed Technical Officer to the Radio Research Board, 463
Brown (S. G.), The Gyrostatic Compass, 44, 77
Brown (Dr. T. Graham), The Function of the Brain, 123
Brown (Prof. W.), The Decay of Magnetism in Bar Magnets, 123; and P. O'Callaghan, The Change in the Rigidity of Nickel Wire with Magnetic Fields, 634
Browne (Dr. E. G.), to deliver the FitzPatrick Lectures, 722
Browne (R. Grant), Races of the Chindwin, Upper Burma, 281
Bruce (Major-Gen. Sir David), The Prevention of Tetanus during the Great War, 785
Brunner, Mond, and Co., Ltd., Purchase of H.M. Nitrate Factory at Billingham-on-Tees, 312; Vote of 100,000*l.* for Scientific Education and Research, 762
Bryan (Prof. G. H.), awarded the Hopkins Prize of the Cambridge Philosophical Society, 440
Bryant (W. W.), The Cost of Scientific Publications, 327; The Position of the Meteorological Office, 38
Bryce (G.), Structure and Development of the Small Woody "Burrs" or "Nodules" in *Hevea brasiliensis*, 20
Bryce (Lord), to receive the Honorary Degree of LL.D. from the University of Dublin, 89
Brylinski (E.), The Transport of Electrical Energy to Great Distances, 347
Buchanan (Capt. A.), Wild Life in Canada, 426
Budge (Sir E. A. Wallis), The "Book of the Dead," 755
Buller (Prof. A. H. R.), Essays on Wheat, 224
Bullock (F.), The Compilation of Bibliographies, 116
Bumstead (Prof. H. A.), elected Chairman of the U.S. National Research Council, 526
Burke (E. T.), The Venereal Problem, 543
Burnet (A.), Conjunction of Mercury with ε Geminorum, 370
Burnside (Dr. W.), awarded the Hopkins Prize of the Cambridge Philosophical Society, 440; Cyclical Octosection, 473
Burrow (E. J.), The Ancient Entrenchments and Camps of Gloucestershire, 128
Burrows (Principal R. M.), [obituary article], 364
Burstall (Prof. F. W.), elected Dean of the Faculty of Science of Birmingham University, 505
Bury (H.), Mortlakes as a Cause of River-windings, 391
Bury (Prof. J. B.), The Idea of Progress: An Inquiry into its Origin and Growth, 733
Butler (Sir Geoffrey), appointed Secretary of the Board of Research Studies in Cambridge University, 345
Butler (S.), Luck, or Cunning, as the Main Means of Organic Modification? An Attempt to Throw Additional Light upon Darwin's Theory of Natural Selection. Second edition, 773; Unconscious Memory. Third edition, 774
Butterworth (S.), The Maintenance of a Vibrating System by means of a Triode Valve, 842

Cadman (Sir John), Impending Resignation of the Chair of Mining in the University of Birmingham, 409; W. B. Hardy, and Prof. S. Young appointed Members of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, 590
Cahen (E.), and W. O. Wootton, The Mineralogy of the Rarer Metals: a Handbook for Prospectors. Second edition, revised by E. Cahen, 259
Caillas (A.), The Search for Invertin in Pure Honey, 218
Cain (Dr. J. C.), The Chemistry and Technology of the Diazo-Compounds. Second edition, 449; The Manufacture of Intermediate Products for Dyes. Second edition, 260
Cajal (S. R. y), elected a Foreign Associate of the U.S. National Academy of Sciences, 463
Cambage (R. H.), A New Species of Queensland Ironbark, 732
Camichel (C.), The Permanent *Régime* in Water-chambers, 314
Campbell (A.), The Magnetic Properties of Silicon Iron (Stalloy) in Alternating Magnetic Fields of Low Value, 473
Campbell (D. F.), Recent Developments of the Electric Furnace in Great Britain, 695
Campbell (Prof. D. H.), Derivation of the Flora of Hawaii, 217
Campbell (R. E.), Distribution, Life History, and Measures of Control of *Bruchus rufimanus*, Boh, 310
Campbell (Prof. W. W.), and J. H. Moore, Researches on Nebulæ, 490
Cannon (H. G.), Production and Transmission of an Environmental Effect in *Simocephalus vetulus*, 538
Cannons (H. G. T.), Bibliography of Industrial Efficiency and Factory Management, 641
Carmody (Prof. P.), Camphor-growing in the British Empire, 757
Carnot (A.), [obituary], 555
Carnwath (Dr.), Influenza, 151
Carpenter (Dr. G. D. H.), The Bionomics of *Glossina palpalis* on Lake Victoria, 663
Carpenter (Prof. G. H.), elected Secretary of the Royal Irish Academy, 590; Injurious Insects observed in Ireland during the years 1916-18, 634; and F. J. S. Pollard, Presence of Lateral Spiracles in the Larvæ of Warble-flies, 835
Carpenter (Prof. H. C. H.), The Future of the Iron and Steel Industry in Lorraine, 588; and Prof. G. C. Cullis, Report on the World's Production of Silver, 73
Carr (Prof. H. Wildon), Behaviourism, 512
Carruthers (D.), The Heart of a Continent, 330
Case (Prof. E. C.), The Environment of Vertebrate Life in the Late Paleozoic in North America, 223
Casella and Co., Ltd. (C. F.), Catalogue of Meteorological Instruments, 20
Cassel (Sir Ernest), Educational Trust Gifts to the University of London, 25
Cattell (Dr. J. McK.), Methods, 795
Cave (Capt. C. J. P.), A Peculiar Halo, 171; Weather Notes of Evelyn, Pepys, and Swift in Relation to British Climate, 393; and J. S. Dines, Soundings with Pilot Balloons in the Isles of Scilly, 663
Cayeux (L.), The Hettangian Iron Minerals of Burgundy, 443
Cellerier (M.), The Verification of Screw Gauges, 184
Cesàro (Prof. G.), Minerals from Monte Somma and Vesuvius, 464
Chadwick (J.), elected to the Clerk Maxwell Scholarship in Experimental Physics in Cambridge University, 601
Chalmers (Mrs. A. J.), awarded a Mary Kingsley Medal, 697
Chalmers (Dr. A. J.), [obituary article], 271
Chalmers (Dr. A. K.), appointed Head of the Health Department of Glasgow, 19
Chalmers (T. W.), Paper-making and its Machinery: including Chapters on the Tub-sizing of Paper, the Coating and Finishing of Art Paper, and the Coating of Photographic Paper, 480
Chamberlin (R. V.), *Priapulus humanus*, 786
Chamberlin (Prof. T. C.), awarded the Hayden Memorial Medal of the Academy of Natural Sciences of Philadelphia, 399
Chapman (D. L.), The Separation of the Isotopes of Chlorine, 487, 611

Chapman (F.), awarded the David Syme Prize and Medal, 496
Chapman (Prof. S.), The Effects of Lunar Tides on the Earth's Atmosphere, 506; and E. A. Milne, The Composition, Ionisation, and Viscosity of the Atmosphere at Great Heights, 570
Chardin (P. T. de), The Piltdown Remains, 593
Charpy (G.), The Minute Fissures in Steel Ingots, 27
Châtelier (H. L. le), elected an Honorary Member of the Royal Irish Academy, 113
Chaudron (G.), Reversible Reactions of Water on Tungsten and the Oxides of Tungsten, 411
Cheney (W. L.), The Measurement of Hysteresis Values when using High Magnetising Forces, 838
Cherry (Major T.), The Origin of Agriculture, 474
Chevalier (A.), Plans for the Reorganisation and Extension of Scientific Services in French Indo-China, 401
Chevenard (P.), The Elasticity of Torsion of Nickel-Steels with a High Proportion of Chromium, 699; The Thermal Change of the Elastic Properties of Nickel-Steels, 603
Chick (Dr. Harriette), awarded the Stewart Prize of the British Medical Association, 432
Chinnery (A. W. P.), awarded the Cuthbert Peek Grant of the Royal Geographical Society, 112
Chirol (Sir Valentine), The Enduring Power of Hinduism, 834
Chisholm (G. G.), Dr. J. G. Bartholomew, 238; Dr. J. G. Bartholomew and the Layer System of Contour Colouring, 328
Chofardet (P.), Observations of the Periodic Comet Tempel II. (Schaumasse) 1920a, 794

Lamb (C. G.), Notes on Magnetism, 193
Lamb (Prof. H.), elected an Honorary Fellow of Trinity College, Cambridge, 88
Lamb (J.), The Running and Maintenance of the Marine Diesel Engine, 290
Lamplugh (G. W.), Anticlinal Uplift the Sequel to Deposition in a Gradually Deepening Trough, 338; Some Features of the Pleistocene Glaciation of England, 58
Lang (H., The Pygmies of Central Africa, 367
Lang (Dr. W. D.), Old Age and Extinction in Fossils, 212
Langmuir (I.), Theories of Atomic Structure, 261
Lankester (Sir E. Ray), Museums and the State, 100; Presentation to, of the Gold Medal of the Linnean Society, 526; Progress!, 733; re-elected President of the Marine Biological Association, 303; Some Rostro-carinate Flint Implements and Allied Forms, 631
Lapicque and Brocq-Rousseu, Marine Algæ as Food for the Horse, 635
Lapworth (Prof. A.), Latent Polarities of Atoms and Mechanism of Reaction, with Special Reference to Carbonyl Compounds, 346
Lapworth (Prof. C.), [death], 76; [obituary article], 110
Larmor (Sir Joseph), elected a Corresponding Member of the French Academy of Sciences, 113; Oration in Presentation of an Honorary Degree to, 568
Latter (O. H.), Note on the Habits of the Tachinid Fly, *Sphexapata (Miltogramma) conica*, 614
Laucks (I. F.), Commercial Oils: Vegetable and Animal, with Special Reference to Oriental Oils, 132
Lavington (F.), appointed Girdlers' Lecturer in Economics in Cambridge University, 601
Laws (B. C.), Conferment of the Degree of D.Sc. upon, by the University of London, 409
Layard (Miss Nina F.), Worked Flints with Finger-grips, 557
Lazarus-Barlow (Dr. W. S.), appointed Professor of Experimental Pathology at Middlesex Hospital Medical School, 698
Le Bon (G.), Certain Antagonistic Properties of Various Regions of the Spectrum, 571
Lecat (Dr. M.), La Tension de Vapeur des Mélanges de Liquides: L'Azétropisme. Première Partie, 129
Lee (H. A.), and H. S. Yates, The "Pink Disease" in the Philippines, 115
Lee (Miss R. M.), The Scale-markings of Fishes, 275
Leechman (D.), The Present State of the Patent Law in the Light of the New Patent Act, 366

Leffingwell (E. de K.), The Canning River Region, Northern Alaska, 559
Lefroy (Prof. H. Maxwell), The Plumage Bill and Bird Protection, 168; and others, The Education of Economic Entomologists, 503
Legroux (R.), and J. Mesnard, Vitamines for the Culture of Bacteria, 315
Leiper (Prof. R. T.), awarded a Mary Kingsley Medal, 697
Leishman (Sir William), to Deliver the Horace Dobell Lecture, 722
Lemarchands (M.), The Reactions of the Metallurgy of Zinc, 282
Lempriere (Dr.), Indices of Physical Progress, 26
Leonard (A. G. G.), and Agnes Browne, Some Derivatives of Nitrotoluidine, 634
Leslie (C. D.), [obituary], 19
Lespieau and Borguel, Production of True Acetylene Hydrocarbons starting from Epidibromhydrin, 635; and Garreau, The Phenylpropines, 699
Lester (J. H.), elected Chairman of the Chemical Section of the Manchester Literary and Philosophical Society, 335
Levi-Civita (T.), Harmonics in the Neighbourhood of an Assigned Function, 844
Levinstein (Dr. H.), The Close Co-operation of the German Government and the "Interessen Gemeinschaft," 722
Lewes (the late Prof. V. B.), and Prof. J. S. S. Brame, Service Chemistry. Fifth edition, 287
Lewis (Dr. T.), appointed Oliver Sharpey Lecturer of the Royal College of Physicians of London, 1921, 755
Litapin (N.), An Easy Method of Finding Latitude, 625
Licent (E.), Use of Mixtures of Formal and Chromium Compounds as Fixing Agents, 604
Lillie (Prof. F. R.), Problems of Fertilisation, 225
Lindsay (Prof. W. M.), elected a Fellow of the Royal Danish Society of Science, 209
Ling (A. R.), appointed Adrian Brown Professor of Brewing in Birmingham University, 154
Link (Dr. H. C.), Employment Psychology: The Application of Scientific Methods to the Selection, Training, and Grading of Employees, 673
Lister (Lord), Commemorating the Work of, 654
Littlewood (J. E.), appointed Cayley Lecturer in Mathematics in Cambridge University, 505
Lewellyn (Dr. T. L.), and others, Lighting Conditions in Mines, with Special Reference to the Eyesight of Miners, 21
Lloyd (L.), The Destruction of the Glasshouse Tomato Moth, 629
Lloyd (S. L.), Mining and Manufacture of Fertilising Materials, and their Relation to Soils, 4
Lockhart (Dr. R. D.), appointed a Lecturer in Anatomy in Aberdeen University, 730
Lockyer (Sir Norman), Contributions to Astrophysics, 831; [obituary articles], 781, 784
Lockyer (Major W. J. S.), Central Wireless Station for Astronomy, 454; Helium: Its Discovery and Applications, 360; Recent Researches on Nebulæ, 489
Loder (Sir Edmund Giles), [obituary article], 301
Lodge (Sir Oliver), Prof. A. Righi, 753
Lones (Dr. T. E.), Zinc and its Alloys, 193
Loring (Capt. F. C.), Announcement that the Post Office is in Favour of Granting Wireless Licences for Experimental Work, 80
Louis, (Prof. H.), British Iron Ores, 419
Lounsbury (C. P.), Legislation in Regard to Plant Pests in the British Empire, 502
Love (Prof. A. E. H.), A Treatise on the Mathematical Theory of Elasticity. Third edition, 511; elected an Honorary Member of the Royal Irish Academy, 113
Lowe (H. J.), Bees and the Scarlet Runner Bean, 742
Lowell (Dr. A. L.), The Honorary Degree of Doctor of Law Conferred upon, by Cambridge University, 730
Lowry (Dr. T. M.), appointed Professor of Physical Chemistry in Cambridge University, 630; and F. C. Hemmings, The Properties of Powders, 217; and S. Wilding, The Setting of Dental Cements, 217
Lucas (A.), Legal Chemistry and Scientific Criminal Investigation, 772
Lumière (A.), Are Vitamines Necessary to the Development of Plants?, 795
Lundmark (K.), The Parallaxes of Globular Clusters and Spiral Nebulæ, 215
Lunn (A. C.), The Commutativity of One-parameter Transformations in Real Variables, 667
Lunt (Dr. J.), The Expanding Disc of Nova Aquilæ, 595; The Spectrum of η Argûs, 149
Lyons (Col. H. G.), appointed Director and Secretary of the Science Museum, South Kensington, 463
Lyster (A. G.), [obituary], 143

MacAlister (Sir Donald), to Receive the Honorary Degree of LL.D. from the University of Dublin, 89
MacArthur (J. S.), [obituary], 112
MacBride (Prof. E. W.), Museums and the State, 68; The Method of Evolution, 655
MacCallum (Dr. Bella D.), appointed Assistant in Botany in Edinburgh University, 120
MacDougal (Dr. D. T.), The Components and Colloidal Behaviour of Protoplasm, 795
MacDougall (Dr.), Insects in Relation to Afforestation, 503
MacFadden (Dr.), Work of Inspectors of Food, 151
Macgregor (M.), and others, The Iron Ores of Scotland. Vol. xi., 419
MacIntyre (Dr. J.), Degree of LL.D. conferred upon, by Glasgow University, 568
Mackenzie (Col. J. S. F.), A Night Raid into Space: The Story of the Heavens told in Simple Words, 100
Mackenzie (K. J. J.), Cattle and the Future of Beef Production in England. With a Preface and Chapter by Dr. F. H. A. Marshall, 62
Mackenzie (Sir Leslie), presented with the Medal of Honour of the University of Brussels, 440
MacLachlan (Dr. N. W.), The Testing of Bars of Magnet Steel, 122
Maclaurin (Dr. R. C.), [obituary], 144
MacMahon (Major P. A.), Congruences with Respect to Composite Moduli, 474
MacMichael (H. A.), Stone Worship, 115

Zanghelis (C.), A New View of the Nascent State, 339; New Researches on the Action of Gases in a very Fine State of Division, 763; and B. Papaconstantinou, Colloidal Rhodium, 411; The Acceleration of the Decomposition of Hydrogen Peroxide by Colloidal Rhodium, 443

TITLE INDEX.

Aberdeen University: W. G. Craib appointed Professor of Botany in, 120; Gift to, by Sir Thomas Jaffrey; Conferment of an Honorary Degree upon Sir Jagadis Chandra Bose, 154; Dr. R. D. Lockhart appointed a Lecturer in Anatomy, 730
Aborigines of Central Australia, The Present Condition of the, E. N. Fallaize, 601
Absorption: Based on the Properties of the Nitrophenols, F. Vlès, 506; Light by Elements in the State of Vapour, Sir James Dobbie and J. J. Fox, 538
Abstracts of Papers in Scientific Transactions and Periodicals, 758
Academic Research and Industrial Application, 449
Académie Royale de Belgique, Sir W. J. Pope elected an Associate of the, 463
Academy, The Royal, 300
Acarina of the Intertidal Zone, J. N. Halbert, 474
Acetone, Preparation of, by the Fermentation of Starchy Material, J. Reilly, and others, 466
Acetylene Hydrocarbons, The Production of True, starting from Epidibromhydrin, Lespieau and Bourguel, 635
Acids, Alkalis and Salts, G. H. J. Adlam, 705
Acmopyle pancheri, Bilger, Structure, and Affinities of, B. Sahni, 346
Actinometers of Arago and Bellani, The, L. Besson, 283
Acylketimines, C. Moureu and G. Mignonac, 539
Adelaide University, Dr. J. B. Cleland appointed Professor of Pathology in, 217
Admiralty, F. E. Smith appointed Director of Scientific Research to the, 344

Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, Sir John Cadman, W. B. Hardy, and Prof. S. Young appointed Members of the, 590
Aerial Navigation and Meteorology, Lt.-Col. E. Gold, 775; Prof. E. van Everdingen, 637, 776
Aerodynamics, Applied, L. Bairstow, 95; of a Spinning Shell, The, R. H. Fowler, E. G. Gallop, C. N. H. Lock, and H. W. Richmond, 377
Aerography, The Principles of, Prof. A. McAdie, 479
Aeronautical Research, 95, 342
Aeronautics: Education and Research in, Report of the Committee on, 15; Lectures on, at the Imperial College of Science and Technology, Sir Richard Glazebrook, 214; Research in, The Relationship of Education to, 14; Report of the Advisory Committee for Aeronautics for the year 1918–19, 561
Aeroplane: Flight: along Africa from North to South, Col. van Ryneveld and Capt. Brand, 113; From Cairo to the Cape, Failure of the, 18; Height Flight, Record, Major R. W. Schroeder, 18
Aeroplanes, Wireless Telephony in, Major C. E. Prince, 55
Afforestation, National, A. D. Webster, 577
African: Art, H. V. Hall, 180; Softwoods for Pulp Production, A. H. Unwin, 599
Agricultural: Development in the West Indies, 344; Research, American, 310
Agriculture: and the Farming Business, O. H. Benson and G. H. Betts, 35; Basic Slag and its Uses in, Dr. E. J. Russell, and others, 183; The Origin of, Major T. Cherry, 474
Aircraft: in Peace and the Law, Dr. J. M. Spaight, 483; Photography in the Service of Science, H. Hamshaw Thomas, 457
Air: Ministry. Convention for the Regulation of Aerial Navigation (October 13, 1919), 637; Routes, Imperial, Maj.-Gen. Sir Frederic H. Sykes, 359; Service, Science and Research in the, 142; The Optical Properties of, the Blue Sky, and, Lord Rayleigh, 584; The Struggle in the, 1914–18, Major C. C. Turner, 229
Alaria, Prof. K. Yendo, 664
Alaska, Exploration and Illustration of, 147
Alchemy and Chemistry among the Chinese, Dr. J. A. R. Henderson, 474
Alcohol: The Supposed Dynamogenic Power of, J. Athanasiu, 251; The whole Truth About, G. E. Flint, 386
Alcohols, a-Ketonic Tertiary, The Synthesis of, D. Gauthier, 27
Algebra, Projective Vector, An Algebra of Vectors Independent of the Axioms of Congruence and of Parallels, Dr. L. Silberstein, 65
Alignment Diagram for Engineers, A New, D. H. Thomson, 116
Aliments Sucrés. Sucres—Miels—Sirops—Confitures—Sucreries—Sucs et Réglisse, Drs. E. Roux and C.-F. Muttelet, 641
Almost-Atolls, The Small Islands of, Prof. W. M. Davis, 292
Alpine Insolation Effects on Unprotected Wood, Prof. E. Knecht, 90
Alternating: Current Work: An Outline for Students of Wireless Telegraphy, A. Shore, 133; Electric Current, The Transient Process of Establishing a steady, Dr. A. E. Kennelly, 843
Altitudes, Extreme, a Method of Reaching, Prof. R. H. Goddard, 809
Aluminium: Amalgamated, and Aluminium Wire, The Behaviour of, W. Thomson and H. S. Newman, 90; Amalgams, The Filamentous Growths from, W. Thomson and H. S. Newman, 506; Catalytic Action of, in the Preparation of the Chlorobenzenes, J. Meunier, 571; Its Manufacture, Manipulation, and Marketing, G. Mortimer, 805
Allegheny Observatory, Dr. H. D. Curtis appointed Director of the, 366
Alligator Pear, The, 208; Dr. M. Grabham, 517
"All—or—None" in the Auditory Nerve, Dr. W. Perrett, 390
Allotments, The Development and Uses of, Sir Daniel Hall, 371
Alloys of Copper, Zinc, and Nickel, The, L. Guillet, 91
Amanita, Determination of Poisonous Varieties of, by Colour Reactions, J. Barlot, 219
Amber in Antiquity, The Search for, W. J. Perry, 274
American: Agricultural Research, 310; Chemical Society, Dr. F. G. Cottrell awarded the Willard Gibbs Medal of the Chicago Section of the, 526; Dr. E. Solvay elected an Honorary Member of the, 590; Fisheries Society, Forthcoming Jubilee of the, 591; Fossil Vertebrate Animals, Prof. H. F. Osborn, and others, 117; Grape-growing, Manual of, U. P. Hedrick, 674; Museum of Natural History, Report for 1919 of the, Prof. H. F. Osborn, 724; Petroleum Institute, Dr. V. H. Manning appointed Director of Research in the, 527; Pomological Society, Re-organisation of the, by Prof. L. H. Bailey, 623; Tertiary, Pleistocene, and Recent Coral-reefs, T. W. Vaughan, 401
Amines by Catalysis, A New Preparation of, A. Mailhe, 442
Ammonium Phosphomolybdate, Variations of the Composition of, S. Posternak, 347
Amundsen's Trans-Polar Voyage, a Supporting Expedition, for, 82; Further News of, 305
Anæsthesia and Anaphylaxy, W. Kopaczewski, A. H. Roffo, and Mme. H. L. Roffo, 540
Ancient: Camps in Gloucestershire, 128; *Egypt*, Resumption of, 180; Entrenchments and Camps of Gloucestershire, The, E. J. Burrow, 128
Anemometer, A Directional Hot-wire, J. S. G. Thomas, 122
Angiosperms, Reproduction of, Elementary Notes on the, A. H. Church, 162
Anglo-Egyptian Sudan, Entomological Work in the, H. H. King, 503
Animal: Foodstuffs: The World's Supply of, 513; Their Production and Consumption, with a Special Reference to the British Empire, Dr. E. W. Shanahan, 513; Heroes: Being the Histories of a Cat, a Dog, a Pigeon, a Lynx, two Wolves, and a Reindeer, E. Thompson Seton. Fourth impression, 580; Life under Water, Dr. F. Ward, 651; Luminescence and Stimulation, Prof. E. N. Harvey, 843; Nutrition, Institute of Research in, at Aberdeen, Gift to the, by J. Q. Rowett, 80; Products, The Chemistry of, 192
Animals, The Slaughter of, and the Distribution of Meat for Human Consumption, Appointment of a Committee of Inquiry Upon, 591
Anomalous Dispersion of Methyl-violet, etc., J. E. Verschaffelt and R. Crombez, 559
Anopheles plumbeus, Misses Blacklock and Carter, 241
Anselm's Problem of Truth and Existence, Rev. A. E. Davies, 569
Antarctic Anticyclone, The, Dr. G. C. Simpson, 777; R. M. Deeley, 808
Anthocyanins in Plants, Formation of, O. Rosenheim, 402
Anthropology: An Introduction to, Rev. E. O. James, 384; and Economics, Progress in, Sir Edward Brabrook, 530; Suggestions for the Classification of the Subject-matter of, E. N. Fallaize, 626
Anticyclones, R. M. Deeley, 677
Anti: -Dumping Bill, The, 125; -Gas Fan, Neglect in Regard to the Use of the, Mrs. Ayrton, 336; 422; 612; 613; Prof. A. J. Allmand, 453; 612
Antineuritic Vitamine, The Nature and Function of the, R. A. Dutcher, 667
Antiquaries of London, Society of, Election of Officers and Council of the, 273
Antiquity of Human Remains?, How Far can Osteological Characters Help in Fixing the, Prof. A. Keith, 153
Ants, Pseudomyrmine, Feeding Habits of, Prof. W. M. Wheeler and I. W. Bailey, 843
Apalaii Indians of the Amazon, The, W. C. Farabee, 240
Applied Science and Industrial Research, J. W. Williamson, 518; Major A. G. Church, 547
Apprentices in Shipyards and Marine Engineering Works, Education and Training of, 151
Approximate Integration, Some Methods of, and of Computing Areas, Prof. J. B. Dale; R. A. P. Rogers, 138

April Meteor Shower, The, 276
Aquarium Cultures for Biological Teaching, Dr. Monica Taylor, 232
Arawaks, The Central, W. C. Farabee, 159
Arcachon, Ville de Santé, Monographie Scientifique et Médicale, Dr. F. Lalesque, 322
Archæocyathinæ from the Weddell Sea, Dr. W. T. Gordon, 528
Archæological Research, The Prospects of, Sir C. H. Read, 497
Arc Spectra *in vacuo* and Spark Spectra in Helium of Various Elements, Prof. J. C. McLennan, J. F. T. Young, and H. J. C. Ireton, 632
Arcs of Primary Triangulation along the Ninety-eighth Meridian in the U.S. and in Mexico, and on Triangulation in Southern Texas, Connection of the, W. Bowie, 141
Arctic: Expedition, Capt. Roald Amundsen's, 240, 273; Prairies, The, E. Thompson Seton, 426
η Argûs, Spectrum of, Dr. J. Lunt, 149
Aristotelian Society, Dean Inge elected President of the, 622
Arithmetic: for Preparatory Schools, An, with Answers, T. Dennis. Second edition, 67; Revision, Logarithms, Slide Rule, Mensuration, Specific Gravity, and Density, T. Thomas Second edition, 229
Armstrong College, Dr. W. N. Haworth appointed Professor of Organic Chemistry at, 537
Army: Hygiene and its Lessons, Lt.-Gen. Sir Thomas Goodwin, 532; Prior to the Recent War, Gen. Sir John Goodwin, 52; The New, Science and, 61; Col. E. H. Hills, 103; Prof. L. N. G. Filon; Prof. R. Whiddington, 133; Lt.-Col. E. Gold,; Dr. C. S. Myers, 135; Prof. A. R. Richardson, 170; Col. K. E. Edgeworth, 233; C. S. Wright, 391; The Scheme for the Education of the Rank and File of the, 121; The Universities and the, 157; F. J. M. Stratton, 234
Arsenic and Antimony Ores, H. Dewey, 338
Arsenious Acid, The Reversible Oxidation of, C. Matignon and J. A. Lecanu, 347
Art, The Teaching of, in Local Museums, M. J. Rendall, 627
Artillery Science, Sir George Greenhill, 268
Asbestos and the Asbestos Industry: The World's Most Wonderful Mineral and other Fireproof Materials, A. L. Summers, 193
Asia, A Geography of, J. Martin, 35
Asiatic Origin of Man, The, W. B. Wright, 728
Aspherical Nucleus Theory Applied to the Balmer Series of Hydrogen, The, Dr. L. Silberstein, 441
Asphodelus, A New Race of, Obtained by the Action of a Marine Climate, L. Daniel, 506
Association: of Technical Institutions, Forthcoming Summer Meeting of the, 631; of University Teachers, Prof. J. Strong elected President of the, 537
Asteroxylon Mackiei from the Rhynie Chert-Bed of Aberdeenshire, Dr. Kidston and Prof. Lang, 527
Astrographic Catalogue, The, 403
Astrolabe: Diagram, Dr. J. Ball, 329; A Handbook of the Prismatic, Dr. J. Ball and H. K. Shaw, 329
Astronomical Announcements by Wireless Telegraphy, Prof. Kobold, 403

ASTRONOMICAL NOTES.

Comets:
Return of Tempel's Comet, 436; Photographs of the Brorsen-Metcalf Comet, Prof. Barnard, 467; The Planetary Families of Comets, Prof. H. N. Russell, 467; Tempel's Second Periodic Comet, 560; Denning's Comet of 1881 and a Meteoric Shower, Rev. M. Davidson, 560; A New Comet, M. Schaumasse, 658; Tempel's Comet, M. Fayet, 789

Instruments:
A New Spectropyrheliometer and Solar Measurements made with it, W. W. Coblentz and H. Kahler, 625

Meteors:
Bright Meteors, 54; April Meteors, 149; The April Meteor Shower, 276; A Bright Fireball, 370; Commencement of the Great Perseid Shower of Meteors, 595; An Interesting Meteorite, G. P. Merrill, 759

Observatories:
The Madrid Observatory, 213; Memoirs of the Kodaikanal Observatory, vol. i., part ii., 340; Parallax Work at the Sproul Observatory, Dr. Miller, 500; Publications of the Dominion Astrophysical Observatory, Victoria, B.C., vol. i., No. 1, 658; Annual Report for 1920 of the Hill Observatory, Sidmouth, 726; New Solar Radiation Station in Arizona, 726; The Union Observatory, Johannesburg, 759; Stonyhurst Observations in 1919, Rev. A. L. Cortie, 789; Publications of the Astronomical Laboratory at Groningen, No. 29, Prof. J. C. Kapteyn, 838

Planets:
Cape Observations of the Sun, Mercury, and Venus, 183; Conjunction of Jupiter and Neptune, 213; Occultation of a Star by Saturn, Prof. Plassmann and others, 244; Eclipse of the Moon, 276; Mars and Wireless Signals, 276; The Lunar Eclipse, 307; Conjunction of Mars with Spica, 340; Conjunction of Mercury with ϵ Geminorum, A. Burnet, 370; The Planet Jupiter, Rev. T. E. R. Phillips, 500; Mercury an Evening Star, 529; The Lunar Parallax and Related Constants, Prof. W. de Sitter, 529; The New Minor Planet GM, 595

Stars:
Occultation of a Star by Saturn, L. J. Comrie, 22; Total Light of the Stars, P. J. Van Rhijn, 54; Star Clusters, Dr. H. Shapley, 54; The Binary Star p Eridani, B. H. Dawson, 84; Faint Nebulæ, E. P. Hubble, 84; Spectrum of η Argûs, Dr. J. Lunt, 149; Infra-red Spectra of Nebulæ, Dr. K. Burns and W. H. Wright, 149; Capella, Prof. F. Schlesinger and Z. Daniel, 183; A Nova in a Spiral Nebula, Prof. Wolf, 213; Stellar Spectroscopy at the Detroit Observatory, P. W. Merrill, L. Hadley, 244; The Wasting of Stellar Substance, Prof. F. W. Very, 276; The Binary Krueger 60, S. A. Mitchell and C. P. Olivier, 307; The Duplicity of ν Geminorum, Dr. Bernewitz, 340; Conjunction of Mercury with ϵ Geminorum, A. Burnet, 370; Double Stars, J. Jackson, 436; Diffraction Image of a Disc, Dr. H. Nagaoka, 436; The Masses of the Stars, Prof. H. N. Russell, 500; Capture Orbits, Prof. L. Becker, 560; The Expanding Disc of Nova Aquilæ, Dr. J. Lunt, 595; Galactic Condensation, R. T. A. Innes, 759; Discovery of a Nova in Cygnus, W. F. Denning, 838; Parallax of the B-type Star Boss 1517, J. Voûte and others, 838

Sun:
The Total Solar Eclipse of September 20, 1922, A. R. Hinks, 84; The Total Solar Eclipse of 1918, June 8, 117; Cape Observations of the Sun, Mercury, and Venus, 183; Kodaikanal Observations of Prominences, J. and Mrs. Evershed, 340

Miscellaneous:
The Nautical Almanac for 1922, 22; Calendar Reform, A. Philip, M. Flammarion, 22; A Noon Reflector, Prof. C. V. Boys, 117; The Einstein Displacement of Spectral Lines, J. Evershed, C. E. St. John, 244; The Nature of Photographic Images, Dr. Kenneth Mees, 307; Longitude by Wireless Telegraphy, Prof. Sampson, 370; Astronomical Announcements by Wireless Telegraphy, Prof. Kobbold; The Astrographic Catalogue, Tidal Friction and the Lunar and Solar Accelerations, Dr. H. Jeffreys, 403; The Zeeman Effect in Furnace Spectra, A. S. King, 529; An Easy Method of Finding Latitude, N. Liapin, 625; Increasing the Photographic Power of Telescopes, Dr. Shapley, 625; The Date of Easter, 691; Astronomy in Town Planning, H. L. Seymour, 691; The Infra-red Arc Spectra of Seven Elements, C. C. Kiess and W. F. Meggers, 726; The Structure of the Universe, Prof. W. D. MacMillan, 789

Astronomy: At Oxford during the War, Prof. H. H. Turner, and others, 407; Central Wireless Station for, Major W. J. S. Lockyer, [illegible] Descriptive, the

Elements of, E. O. Tancock. Second edition, 131; in Town Planning, H. L. Seymour, 691
Astrophysics, Sir Norman Lockyer's Contributions to, Prof. A. Fowler, 831
Athenæum Club, Prof. C. J. Martin, Sir William Orpen, and Sir J. E. Pelavel elected members of the, 209
Atlantic: Meteorological Influences of the Sun and the, Prof. J. W. Gregory, 715; Ocean, an Oceanographical and Meteorological Atlas of the, Pt. i., 368
Atmosphere: At Great Heights, Composition, Ionisation, and Viscosity of the, Prof. S. Chapman and E. A. Milne, 570; High Levels in the, Attainment of, W. H. Dines, 454; Occurrence of Ozone in the, J. N. Pring, 645
Atmospheric: Circulation, General, The Meteorology of the Temperate Zone and the, Prof. V. Bjerknes, 522; Eddies, the Supply of Energy to, L. F. Richardson, 378; Nitrogen, Rate of Solution of, and Oxygen by Water, Prof. W. E. Adeney and H. G. Becker. Part iii., 379; Potential at the Algiers Observatory, A Diurnal Variation of the, F. Baldet, 283; Turbulence, Some Measurements of, L. F. Richardson, 57; Variations of Short and Long Duration in the Malay Archipelago and Neighbouring Regions, and the Possibility to Forecast Them, Dr. C. Braak, 729
Atomic: and Molecular Forces and Crystal Structure, Dr. A. E. Oxley, 327; and Molecular Structure, on, Dr. A. E. Oxley, 231; Structure, Theories of, I. Langmuir, 261; Theory, The Development of the, A. N. Meldrum, 212; Weights, Isotopes, and, Dr. F. W. Aston, 617; The Standard of, Prof. J. R. Partington, 264; Dr. S. Miall, 294
Atomique, La Théorie, Sir J. J. Thomson; Traduit par Prof. C. Moureu, Nouveau tirage, 36
Atoms: Langmuir's Theory of, S. C. Bradford, 41, 725; Dr. A. E. Oxley, 105; Nuclear Constitution of Atoms, Sir Ernest Rutherford, 500; The Structure of, Prof. A. Berthoud, 306
Attitudes of the Body and Respiration, J. Amar, 635
Auditory Nerve, "All-or-None" in the, Dr. W. Perrett, 390
Aurora: A Brilliant, Observed at Montreal, Prof. A. S. Eve, 337; of March 22-23, The, W. B. Housman, 200
Australia, Agricultural Climatology of, Dr. Griffith Taylor, 442
Australian: Delphacidæ (Homoptera), A New Genus of, F. Muir, 635; Flies of the Family Asilidæ, Synonyms, Notes, and Descriptions of, G. H. Hardy, 635; Hardwoods, 802; Native Fauna, Extermination of the, C. M. Hoy, 558; Rainfall, Tropical Control of, E. T. Quayle, 152
Australischen Sprachen, Die Gliederung der, P. W. Schmidt; S. H. Ray, 707
Auto-ballistic Astronomical Pendulum, An, A. Guillet, 506
Automobile Steels, Research on, 690
Aviation: and Scientific Exploration, Dr. P. Chalmers Mitchell, 336; Civil, Report of the Advisory Committee on, 556; Report of the Department of, 592
Avocado or Alligator Pear, Cultivation of the, W. G. Freeman, 408
Ayrshire Cattle, Milk Production of, Prof. R. Pearl and J. R. Miner, 245

B. coli communis, The Enzymes of, E. C. Grey, 538
Bacteria, The Transmutation of, Dr. S. Gurney-Dixon, 131
Bakerian Lecture, The, Sir Ernest Rutherford, 500
Balmer Series of Hydrogen Lines, The Structure of the, Dr. T. R. Merton, 314
Band Spectra of Nitrogen, Production of the, by Electrons of Low Velocity, L. and E. Bloch, 539
Banks, Sir Joseph, The Centenary of, 406; Dr. B. Drydon Jackson; Dr. A. B. Rendle; J. Britten; Dr. A. Smith Woodward, 410
Barnard Medal of Columbia University, The, awarded to Prof. Einstein, 500
Barytes in the English Triassic Strata derived from overlying Jurassic Strata, H. W. Greenwood, 837
Basic Slag and its Uses in Agriculture, Dr. E. J. Russell; Sir Thomas Middleton, 183; Bainbridge; G. Scott Robertson; D. Sillars, 184
Batu Kurau Parish, Perak, Exploration of a Rock Shelter in the, I. H. N. Evans, 834
Bedford College for Women, Appeal for Funds by, 180
Bee-Eater in Scotland, Nesting of the, J. K. Nash, 780
Bees: Eye-Colour in, Prof. T. D. A. Cockerell, 518; and the Scarlet-Runner Bean, H. J. Lowe, 742
Beetles, Indian, 64
Behaviourism, Prof. H. Wildon Carr, 512
Beit Fellowship for Scientific Research, M. A. Hogan elected to a, 665
Belfast, Queen's University: Dr. J. Small appointed Professor of Botany in, 25; Gift to, by F. A. Heron, 248
Belgian Congo Territory, Zoological Collections made in the, during 1909–15, 593
Bengal, Biological Papers from, Dr. N. Annandale, 436
Benzene: Chlorination of, Kinetic Study of the, F. Bourion, 506; extracted from Commercial Chlorobenzenes, Impurities of the, F. Bourion, 443
Benzoic Acid, A Reaction for, based on its Diazotisation, M. Guerbet, 666
Benzoylphenylacetylene di-iodide, The Stereo-isomeric forms of, C. Dufraisse, 475
Beri-Beri, The Pathology and Symptomatology of, Dr. F. M. R. Walshe, 241
Bibliographies, The Compilation of, F. Bullock, 116
Bicycle, The Evolution of the, Prof. W. W. Watts, 435
Billingham-on-Tees, Sale of the Nitrate Factory at, to Brunner, Mond and Co., Ltd., 312
Biological Papers from Bengal, Dr. N. Annandale, and others, 436
Bipolar Co-ordinates, Plane Stress and Plane Strain in, G. B. Jeffery, 632
Bird: Life, The Romance of, 746; Protection, The Plumage Bill and, Sir H. H. Johnston; Prof. H. M. Lefroy, 168; Sir Herbert Maxwell; Prof. A. Dendy, 169; Dr. W. E. Collinge, 196; Prof. J. E. Duerden, 263
Birds: and Beasts, The Story-Book of, J. H. Fabre, 651; in Town and Village, W. H. Hudson, 651; Life and Lore of, 514; of Eastern Canada, The, P. A. Taverner, 623; of Egypt, Hand-List of the, M. J. Nicoll, 674; of the British Isles, The, and their Eggs, T. A. Coward. First series, 132
Birkbeck College, A Course of Training for ex-Service Men for Positions on Rubber and Tea Plantations, 280
Birmingham University: A. A. Dee appointed an Assistant Lecturer in Physics in, 120; A. R. Ling appointed Adrian Brown Professor of Brewing, Erection of a Memorial Tablet to Prof. Adrian Brown; Gift from the Asiatic Petroleum Co.; F. Shaw appointed Assistant Lecturer in Electrical Engineering, and R. B. H. Wyatt Lecturer in Bacteriology, 154; Impending Resignation of Sir John Cadman of the Chair of Mining, 409; Students in, 472; The Department of Mining to be re-organised and extended; Prof. F. W. Burstall elected Dean of the Faculty of Science, 505; Conferment of Degrees, 630; Increase in Cost of Fees; The Necessity for Increasing the Stipends of the Staff, Sir Gilbert Barling, 730
Birth-Rate, The, W. L. George 82
Bitterns, Buzzards and, Canon E. McClure, 105
Black Smoke Tax, The, 471
Blepharospora terrestris, A Parasite of the Lupin, B. Peyrouel, 844
Blood, The Circulating, in Relation to Wound-Shock, Prof. W. M. Bayliss, 9
Blow-flies, Experiments in Breeding, Prof. Enriques, 756
Board of Trade, Dr. Edridge-Green appointed a Special Examiner in Colour Vision and Eyesight by the, 654
Body Temperatures, Electrical Methods of Measuring, R. S. Whipple, 338
"Book of the Dead," The, Sir E. A. Wallis Budge, 755
Books, Scientific and Technical, Sir R. A. Gregory, 41
Boss 1517, Parallax of the B-type, J. Voûte, and others, 838
Botanical Guides, 34
Botany: Applied, G. S. M. Ellis, 164; Applied Economic, Based upon Actual Agricultural and Gardening Projects, Dr. M. T. Cook, 34; A University Course in, 162; Structural, Elementary Notes on, A. H. Church, 162

Botrytis cinerea, with colourless sclerotia, A Form of, W. B. Brierley, 186
Bowl, a Remarkable Stone, in the Museo Arqueológico, Madrid, B. G. Corney, 755
Brachyphalangy, Hereditary, in Man, A New Type of, O. L. Mohr and C. Wriedt, 464
Bradford Technical College, H. Richardson appointed Principal of the, 505
Brain, The Function of the, Dr. T. G. Brown, 123
Brass, 60-40, Some Properties of, Prof. C. H. Desch, 695
Brent Valley Bird Sanctuary, The, W. M. Webb, 614; 622
Bristol University: Forthcoming Award of the Vincent Stuckey Lean Scholarship; Proposed Extensions of the Engineering Faculty, 313; Prof. F. Francis appointed Pro-Vice-Chancellor, 601; Resignation of Prof. F. Francis as Dean of the Faculty of Science; Prof. A. M. Tyndall appointed Dean of the Faculty of Science, and P. Fraser Deputy Dean; Prof. C. Lloyd Morgan appointed Emeritus Professor of Psychology and Ethics; Dr. C. D. Broad appointed Professor of Philosophy, 630
British: Aeronautics, 561; and Foreign Scientific Apparatus, D. H. Baird, 390; J. W. Ogilvy, 424; J. S. Dunkerly, 425; F. W. Watson Baker, 518; Prof. W. M. Bayliss, 641; and Metric Systems of Weights and Measures, A. S. E. Ackermann, 456; Association, The Sectional Presidents of the Cardiff Meeting of the, 112; Forthcoming Meeting of the, 399; The Cardiff Meeting of the, 524, 780; Subjects for Discussion at the Cardiff Meeting, 626; Bequest to, by T. W. Backhouse, 630; Presidential Address, Prof. W. A. Herdman, 813; Summaries of Addresses of the Presidents of Sections, 825; The Meeting at Cardiff, 830; Astronomical Association, Bequest to, by T. W. Backhouse, 631; Chemical Mission on Chemical Factories in the Occupied Area of Germany, A Summary of the Report of the, 253; Chemists, Central Headquarters for, 697; Cotton Industry Research Association, pending Scientific Appointments by the, 274; Constitution and Methods of the, Dr. A. W. Crossley, 372; First Annual Report of the, 840; Crop Production, Dr. E. J. Russell, 176, 206; Dyes Corporation, Sir Henry Birchenough appointed Chairman of the, 303; East Africa, Profit and Sport in, being a Second Edition, revised and enlarged, of "A Colony in the Making," Capt. the Lord Cranworth, 392; The Development of, 392; Empire, Cotton-Growing in the, Dr. W. Lawrence Balls, 103; Sir George Watt, 104; Exhibition, The Forthcoming, 755; Forestry Conference, The Principal Members of the, Received by the King, 687, 759; Order of the, Promotions and Appointments of the, 144; Sugar Research Association, The, 80; Timber Exhibition, The, 591; India, The Fauna of, including Ceylon and Burma, Coleoptera, Chrysomelidae (Hispinae and Cassidinae), Prof. S. Maulik, 64; Iron Ores, Prof. H. Louis, 419; Isles and North-West Europe, Practical Exercises on the Weather and Climate of the, W. F. Stacey, 133; The Birds of the, and their Eggs, T. A. Coward, First Series, 132; The Colour Index of the, Prof. F. G. Parsons, and others, 531; *Journal of Experimental Pathology*, No. 1, 82; Lampblown Scientific Glassware Manufacturers' Association, Ltd., History of the Formation of the, D. H. Baird, 406; Motor Cycle and Cycle Car Industry, The Research Association for the, Approved, 526; Ornithology from the Earliest Times to the end of 1918, A Geographical Bibliography of, W. H. Mullens, H. Kirke Swann, and Rev. F. C. R. Jourdain. Part I., 353; Research Association for the Woollen and Worsted Industries, Report of, for 1918-19, 118; Rubber and Tyre Manufacturers, Research Association of, B. D. Porritt appointed Director of Research by the, 170; School of Archaeology in Jerusalem, The Prince of Wales Patron of the, 52; Science Guild, The Forthcoming Annual Meeting of the, 308; Annual Meeting of the, 368; Journal of the, June, 657; Sea Fisheries, The, 307
Bromohydrins and Dibromo-derivatives, A. Haller and Mme. Ramart-Lucas, 762
Brorsen-Metcalf Comet, Photographs of the, Prof. Barnard, 467
Bruchus rufimanus, Boh, Distribution, Life-History, and Measures of Control of, R. E. Campbell, 310
Brussels University, The Medal of Honour Presented to Lord Dawson of Penn, Sir Leslie Mackenzie, and Prof. Sir William Smith, 440
Buddhism in the Pacific, Sir Henry Howorth, and others, 407
Buenos Aires, Discovery of Early Remains of Man in, Dr. C. Ameghino, 209; National Museum of Natural History, Dr. C. Ameghino appointed Director of the, 80
Butter and Cheese, C. W. W. Tisdale and J. Jones, 738
Buzzard at Home, The, A. Brook, 746
Buzzards and Bitterns, Canon E. McClure, 105
Bygone Beliefs: Being a Series of Excursions in the Byways of Thought, H. S. Redgrove, 610

Cairo, Proposed University at, 731
Calcium, The Absorption of, by Plant-Roots and its Antitoxic Properties towards Copper, L. Maquenne and E. Demoussy, 91
Calculus: Differential for Colleges and Secondary Schools, Dr. C. Davison, 65; Elementary, C. H. P. Mayo (with answers), 163
Calcutta, Report for 1918-19 of the Bureau of Education, 794
Calendar Reform, A. Philip, C. Flammarion, 22; C. Flammarion, Dr. A. C. D. Crommelin, 105
Camarasaurus, Cope (Morosaurus, Marsh), Reconstruction of the Skeleton of, H. F. Osborn and C. C. Mook, and Restoration of the Camarasaurus and Life-Model, W. K. Gregory, 667
Cambrian Horizons of Comley (Shropshire), The, and their Brachiopoda, etc., E. S. Cobbold, 314
Cambridge University: Girton College, Offer of a Fellowship by, 25; E. V. Appleton appointed an Assistant Demonstrator in Experimental Physics; Proposal to Create a Readership in the Morphology of Vertebrates and a Lectureship in Zoology; New Building Schemes, 56; Prof. H. Lamb, Sir Thomas L. Heath, Prof. W. H. Bragg, and Dr. H. Head elected Honorary Fellows of Trinity College; A. Amos appointed University Lecturer in Agriculture, and G. U. Yule re-appointed University Lecturer in Statistics, 88; A Smith's Prize awarded to S. Pollard; Grants from the Gordon-Wigan Fund, 88; Fresh Regulations for the Diplomas in Agriculture and Forestry Drafted, 89; Two Exhibitions Offered by Emmanuel College; Approval of the New Statute Authorising the Degree of Doctor of Philosophy for Research, 120; F. B. Smith appointed Reader in Estate Management in, 120; G. E. Briggs elected to the Allen Scholarship; The New Ph.D. Statute, 154; Gifts towards the Hopkinson Professorship in Thermodynamics; The Linacre Lecture to be delivered by Dr. H. Head; Proposed Honorary Degrees, 312; The Sheepshanks Exhibition in Astronomy awarded to E. S. Pearson; Examination for the Diploma in Medical Radiology and Electrology; H. Hamshaw Thomas re-appointed Curator of the Botanical Museum; Bequest by the Hon. Sir Charles A. Smith to Peterhouse, 313; Report of Syndicate on the Relation of Women Students; Sir Geoffrey Butler appointed Secretary of the Board of Research Studies; H. F. Gadow appointed Reader in the Morphology of Vertebrates; Dr. H. Scott Curator in Entomology; G. F. C. Gordon Superintendent of the Engineering Workshops; L. G. P. Thring Superintendent of the Engineering Drawing Office, 345; E. A. Milne appointed Assistant Director of the Solar Physics Observatory; The First M.B. Examination; Relation of Women to the University; The Local Lectures Summer Meeting, 376; Conferment of Honorary Degrees, 409; Prof. J. T. Wilson appointed Professor of Anatomy, 439; Hopkins Prize Awards

made to Dr. W. Burnside, Prof. G. H. Bryan, and C. T. R. Wilson, 440; Dr. T. G. Adami elected an Honorary Fellow of Christ's College, 440; Offer for the Erection, etc., of a Low-Temperature Station, 440; Gift for a Biochemistry Building, 472; The Gift for the Sir William Dunn School of Biochemistry; Dr. T. G. Adami elected an Honorary Fellow of Jesus College; J. E. Littlewood appointed Cayley Lecturer in Mathematics; J. H. Grace reappointed University Lecturer in Mathematics, 505; Substitution of Thermodynamics for Elementary Optics in Schedule A of Part II. of the Mathematical Tripos Recommended; Proposed Honorary Degrees, 505; A Course for a Degree in Horticulture, 506; An *ad interim* grant by the Government; Donation Received for Lectures in Tropical Agriculture; Dr. C. A. Barber appointed Lecturer in Tropical Agriculture; Miss B. A. Clough appointed Principal of Newnham College, 537; Dr. Adrian appointed University Lecturer in Physiology; F. A. Potts University Lecturer in Zoology; E. W. Ravenshear awarded the Harkness Scholarship; R. E. Holthum and G. T. Henderson, Frank Smart Prizes, 537; Dr. F. W. Aston elected to a Fellowship in Trinity College; Latin Orations at the Presentation of Sir Joseph Thomson and Sir Joseph Larmor for Honorary Degrees, 568; Bequest by Rev. E. S. Marshall, 601; Dr. S. Scales appointed University Lecturer in Medical Radiology and Electrology; F. Lavington appointed Girdlers' Lecturer in Economics; J. Chadwick elected to the Clerk Maxwell Scholarship in Experimental Physics; H. F. Holden to the Benn W. Levy Research Studentship in Biochemistry; A. J. Beamish to the Wrenbury Scholarship in Economics, 601; Dr. T. M. Lowry appointed Professor of Physical Chemistry, 630; Further Gift by Mr. and Mrs. P. A. Molteno towards the Cost of the Molteno Institute of Parasitology; R. H. Vernon appointed Assistant to the Professor of Chemistry; Impending Conferment of Honorary Degrees, 665; The Balfour Memorial Fund Studentship; The Honorary Degree of Doctor of Law Conferred upon Dr. A. L. Lowell, Prof. J. J. Abel, and Prof. H. Cushing, 730; Prof. S. J. Hickson elected an Honorary Fellow of Downing College; A. J. Berry re-elected to a Fellowship, 761; Presentation to Dr. W. L. H. Duckworth, 794

Cameron Prize of the University of Edinburgh, The, Awarded to Sir Robert Jones, 622

Camphor-growing in the British Empire, Prof. P. Carmody, 757

Canada: and the United States, A Summer Tour (1919) through the Textile Districts of, Prof. A. F. Barker, 780; Arctic, Insects of, 730; Natural History Studies in, 426; Summary Report of the Mines Branch of the Department of Mines of, for the year 1918, 242

Canadian: Arctic Expedition, 1913-18, Reports on Crustacea, Prof. A. Willey and Dr. C. Juday, 835; Progress, Fifty Years of, E. H. Godfrey, 147; Water-power Development, L. G. Dennis, 311

Cancer: Effect of Physical Agents on the Resistance of Mice to, J. B. Murphy, 668; Research Fund, The Imperial, 687, 696

Cane-sugar, The Biochemical Preparation of, starting with Gentianose, Em. Bourquelot and M. Bridel, 666

Cannibalism, The After-effects of, C. E. Stromeyer, 90

Canning River Region, The, Northern Alaska, E. de K. Leffingwell, 550

Canonical Forms, The late E. K. Wakeford, 369

Canvas-destroying Fungus, J. Ramsbottom; Major W. Broughton-Alcock, 563

Capella, Prof. F. Schlesinger and Z. Daniel, 183

Capture Orbits, Prof. L. Becker, 560

Carbon: Bisulphide for Increasing Durations of Charge, The Ratio of the Absolute Retardations in, M. Pauthenier, 699; Dioxide, Prolonged Action of, on Silicates and Quartz, C. Matignon and Mlle. Marchal, 443; Monoxide in the Air of Mines, Apparatus for the Estimation of Small Quantities of, J. I. Graham, 624; Sub-nitride, New Researches on, C. Moureu and J. C. Bongrand, 411

Carbonyl Compounds, Latent Polarities of Atoms and Mechanism of Reaction, with Special Reference to, Prof. A. Lapworth, 346

Carnegie: Corporation of New York, Dr. J. R. Angell elected President of the, 527; Foundation, The, and Teachers' Pensions, 596; Magnetic Observations taken on the, in February and March, 1920, 788; Results of the Magnetic Survey of the Atlantic made by the, J. P. Ault, 520; United Kingdom Trust, Sixth Annual Report of the, 56

Cass Technical Institute, Sir John, Membership of and Courses at the, Dr. C. A. Keane, 121

Catalase, The Chemical Kinetics of, E. Yamasaki, 402

Catalytic: Action at Solid Surfaces, A Study of the, Dr. E. F. Armstrong and T. P. Hilditch, III. and IV., 314; V., Dr. E. F. Armstrong and T. P. Hilditch, 631; Activity of Copper, Part I., W. G. Palmer, 633; Chemical Reactions and the Law of Mass Action, Dr. E. F. Armstrong, 696; Decomposition of Solutions of Hydrogen Peroxide by Colloidal Platinum, A. de G. Rocasolano, 603; of the Fatty Acids by Carbon, J. B. Senderens and J. Aboulenc, 411; Hydration of Nitriles, The, A. Mailhe, 795

Cattle and the Future of Beef-Production in England, K. J. J. Mackenzie, with a Preface and Chapter by Dr. F. H. A. Marshall, 62

Cawthron Institute, Appointments at the, 590; Dr. R. J. Tillyard, 603

Cells, Multinucleate: An Historical Study (1879-1919), R. Beer and Dr. Agnes Arber, 90

Cellulose Acetate, Studies on, Dr. Fenton and A. J. Berry, 378

Celt and Slav, Prof. J. D. Prince, 763

Celts, Flat-based, from Kent, Hampshire, and Dorset, H. Dewey, 153

Census, The Forthcoming, 707

Central: Asia, Through Deserts and Oases of, Miss Ella Sykes and Brig.-Gen. Sir Percy Sykes, 330; Australia, The Present Condition of the Aborigines of, E. N. Fallaize, 601

Cephalopodes, Researches on the Posterior Salivary Gland of III., F. Bottazzi, 251

Cereal Seeds, Dry Heat Treatment of, D. Atanasoff and A. G. Johnson, 310

Cereals, Estimated Yields of, Throughout the World, 657; The Prospective Yields of, for 1919-20, 147

Cerebral Cortex, Sensation and the, Dr. H. Head, 363

Cerions, Experiments in the Breeding of, P. Bartsch, 545

Ceryl Alcohol and Cerotic Acid from China Wax, A. Gascard, 506

Ceylon Fungi, Revisions of, Part VI., T. Petch, 20

Chadwick Public Lectures, Forthcoming, 20

Chaleur et du Froid, Action de la, sur l'Activité des Etres Vivants, G. Matisse, 161

Cheddar Caves, Plant-Life in, L. Pendred, 709

Chemical: *Age*, Vol. I., 116; Analysis, Quantitative, A Text-book of, Dr. A. C. Cumming and Dr. S. A. Kay, Third Edition, 33; Calculation Tables: For Laboratory Use, Prof. H. L. Wells, Second Edition, 33; Dictionary, Popular, C. T. Kingzett, 227; Engineer, The Training and Functions of the, Lord Moulton, 83; Industry, Society of, The Medal of the, awarded to P. Kestner, 366; Sir William J. Pope elected President of the: The Gold Medal of the, Presented to P. Kestner, 654; Annual Meeting of, 695; Industries of German Rhineland, The, 253; Physiology, The Essentials of, Prof. W. D. Halliburton, Tenth Edition, 192; Research as Applied to Industry, An Impending French Institute for, 722; Notes on, An Account of Certain Conditions which apply to Original Investigation, W. P. Dreaper, Second Edition, 773; Service for India, A, Prof. H. E. Armstrong, 669; Sheet-Lead, D. W. Jones, 695; Society, Proposals for Election of Honorary and Foreign Members, 52; Election of Officers and Council of the, 145; and its New By-laws, 344; Women Made Eligible for Fellowships of the, 432; Text-books, 705; Theory

and Calculations, Profs. F. J. Wilson and I. M. Heilbron, Second Edition, 805
Chemistry: Annual Reports on the Progress of, for 1919, Vol. XVI., 708; and its Mysteries: The Story of what Things are Made of, told in Simple Language, C. R. Gibson, 99; Applied, A Practical Handbook for Students of Household Science, and Public Health, Dr. C. K. Tinkler and Helen Masters, Vol. I., 227; Manuals on, 382; Elementary Agricultural, H. Ingle, Third Edition, 773; Practical, for Medical and other Students, Dr. J. E. Myers and J. B. Firth, Second Edition, 705; for Public Health Students, E. G. Jones, 705; for Textile Students, B. North, assisted by N. Bland, 382; from the Industrial Standpoint, P. C. L. Thorne, 227; French Text-books of, 63; Industrial, New Books on, 227; Institute of, Annual General Meeting of the, 19; Legal, and Scientific Criminal Investigation, A. Lucas, 772; of Coal, The, J. B. Robertson, 382; Organic, A Class-book of, Prof. J. B. Cohen, Vol. II., 195; Physical, Introduction to, Prof. J. Walker, Eighth Edition, 129; Practical, 33; A Course of, for Agricultural Students, Vol. I., L. F. Newman and Prof. H. A. D. Neville, 291; Vol. II., Part I., H. A. D. Neville and L. F. Newman, 33; Leather, A. Harvey, 382; Service, the late Prof V. B. Lewes and Prof. J. S. S. Brame, Fifth Edition, Sir T. E. Thorpe, 287
Chemists: British, Central Headquarters for, 697; Industrial, The National Association of, A. B. Searle elected President of, 785; Year Book, 1920, Edited by F. W. Atack, assisted by L. Whinyates, 2 vols., 740
Child Physiology: The Principles of Ante-Natal and Post-Natal, Pure and Applied, W. M. Feldman, 638
Children, Physical Efficiency of, Investigation and Standardisation of the, Dr. A. A. Mumford, 26
Chile and Argentina, Botanical Exploration in, W. B. Turrill, 433
Chimica delle Sostanze Esplosive, Prof. M. Giua, 483
Chimie: Cours de, à l'Usage des Etudiants P.C.N. et S.P.C.N., Prof. R. de Forcrand, Deuxième édition, Tome I. et Tome II., 63; Organique, Notions Fondamentales de, Prof. C. Moureu, Sixième édition, 63
Chindwin, Upper Burma, Races of the, R. Grant Browne, 281
Chloride of Bromine, The: Its Combination with Ethylene, M. Delépine and L. Ville, 539
Chlorine: and Various Vapours, The Action of, upon Plants, P. Guerin nad Ch. Lormand, 59; The Separation of the Isotopes of, D. L. Chapman, 487, 611; Prof. F. Soddy, 516, 642; The Separation of the Element, into Normal Chlorine and Meta-chlorine, and the Positive Electron, Prof. W. D. Harkins, 230; Dr. F. W. Aston, 231; A. F. Core, 582, 677
Chlorobenzenes, Commercial, Analysis of, by Distillation, F. Bourion, 347
Chloropicrin: Act Upon Soluble Ferments? Does, G. Bertrand and Mme. Rosenblatt, 690; Action of, Upon Yeast and *Saccharomyces vini*, G. Bertrand and Mme. Rosenblatt, 507; Activity of, Towards the Higher Plants, Conditions, which may Modify the, G. Bertrand, 347; Upon Some Bacterial Fermentations, G. Bertrand and Mme. Rosenblatt, 571; Upon the Higher Plants, G. Bertrand, 283; on the Parasites of Wheat and on Rats, A. Piutti, 283
Chondriome of the Vaucheria, The, G. Mangenot, 571
Cinchona: Bark, "Grey," Some Recent Samples of, B. F. Howard and O. Chick, 726; Botanical Station, Continued American Lease of the, 19
Civil: Aviation, Report of the Advisory Committee on, 556; Engineers, Institution of, Awards of the, 303; Election of Officers of the, J. A. Brodie President, 304; List Pensions, Some, 654; Service Estimates for 1920-21, Education and Science in the, 246
Clark University and Clark College, Resignations of Dr. G. Stanley Hall and Dr. E. C. Sanford; Appointment of Dr. W. W. Atwood as Head of Both Institutions, 602
Clifton College Scientific Society, 631
Climate of the Netherlands, 600
Climatic: Cycles and Evolution, Dr. Griffith Taylor, 728; Cycles and Tree-growth, Prof. Douglass, 562
Climatology of North-west Russia and France, 119
Cloud and Sunshine, The Relationship between, J. R. Sutton, 667; Distribution at Aberdeen during the years 1916-18, An Analysis of, G. A. Clarke, 148
Clouds as Seen from an Aeroplane, Capt. C. K. M. Douglas, 218
Cluster Pine, The, Dr. M. Grabham, 675
Clytocosmus, An Undescribed Species of, Skuse (*Tipulidæ, Diptera*), Dr. C. P. Alexander, 635
Coal: Measures in the Central Marsif and at its Edges, The Course of the, L. De Launay, 634; Supplies, Our, The Conservation of, Prof. J. W. Gregory, 108; The Chemistry of, J. B. Robertson, 382; The Oxidation of, M. Godchot, 666
Coastal Limestones of the Cape Province, W. Wybergh, 689
Coke-oven: Construction, Modern By-product, W. A. Ward, 695; and Blast-furnace Gases for Heating and Power, The More Economical Utilisation of the, G. W. Henson and S. H. Fowles, 695; Gas, By-products from, Dr. E. W. Smith, 695; for Town Supply, H. E. Wright, 695; Walls, The Corrosion of, W. J. Rees, 695
Colloid Chemistry, Elementary, Laboratory Manual of, E. Hatschek, 705
Colloidal: Complexes and Sera, G. Riquoir, 187; Electrolytes, Prof. J. W. McBain, 760; Systems, The Properties of, IV.: Reversible Gelation in Living Protoplasm, Prof. W. M. Bayliss, 26; Therapy, 351
Colloids: in Health and Disease, The Use of, A. B. Searle, 351; The Filtration of, Dr. W. R. Ormandy, 606; The Physics and Chemistry of, Forthcoming Symposium and Discussion on, 654
Cologne Post, Anniversary of the, 211
Colour: and Chemical Constitution, Part XI., J. Moir, 667; Blindness, Card Test for, Dr. F. W. Edridge-Green, 575; Index of the British Isles, The, Prof. F. G. Parsons, and others, 531; Vision, The Theory and Facts of, 575
Colouring Matters of Plants, 139
Columbia and Vicinity, Flora of the District of, A. S. Hitchcock and P. C. Standley, 242
Columbian Tradition, The, on the Discovery of America and of the Part Played Therein by the Astronomer Toscanelli, H. Vignaud, 803
Combustibles, The Application Value of, E. Damour, 634
Commercial Parasitism in the Cotton Industry, O. F. Cook, 548
Compass: The Gyrostatic, S. G. Brown, 44, 77; The Mariner's, 44
Complex Combinations: A New Series of, the Antimony Oxyiodides, A. C. Vournazos, 475
Compositæ: Ancestral Studies of, 450; The Origin and Development of the, Dr. J. Small, 450
Concrete, Light, C. Rabut, 91
Conflict, The Philosophy of, and other Essays in Wartime, Havelock Ellis, Second Series, 353
Congress, Librarian of, Report of the, for the year ending June 30th, 1919, 537
Congruences with respect to Composite Moduli, Major P. A. MacMahon, 474
Conic Curves, A New Apparatus for Drawing, A. F. Dufton, 187
Conjoint Board of Scientific Societies, Report for 1919, 343
Conquest, August, 756
Continent, The Heart of a, D. Carruthers, 330
Continuation Schools and their Relation to Technical Institutes and Colleges, Principal C. L. Eclair-Heath, 728
Contour Colouring, the Layer System of, Dr. J. G. Bartholomew and, G. G. Chisholm, 328
Coolidge Tube: The Manufacture of the, Dr. W. D. Coolidge, 655; The Radiator Dental Type of, 758; Its Scientific Applications, Medical and Industrial, H. Pilon translated, 739
Copper: A Case Favourable to the Action of, on Vegetation, L. Maquenne and E. Demoussy, 634; in Plants, The Presence of, and particularly in food of Vegetable Origin, B. Guérithault, 763

Corallimorphus, The Genus, T. A. Stephenson, 474
Correlation Coefficient, Partial, in Samples of 30, An Experimental Determination of the Distribution of the, J. W. Bispham, 187

CORRESPONDENCE.

Aerial Navigation and Meteorology, Lt.-Col. E. Gold, 775; Prof. E. van Everdingen, 776
Alligator Pear, The, Dr. M. Grabham, 517
"All-or-None" in the Auditory Nerve, Dr. W. Perrett, 390
Almost-Atolls, The Small Islands of, Prof. W. M. Davis, 292
Antarctic Anticyclone, The, Dr. G. C. Simpson, 777; R. M. Deeley, 808
Anticyclones, R. M. Deeley, 677
Anti-Gas Fans, Mrs. Hertha Ayrton, 422, 612, 613; Prof. A. J. Allmand, 453, 612
Applied Science and Industrial Research, J. W. Williamson, 387, 518; Prof. F. Soddy, 422; Major A. G. Church, 423, 547
Aquarium Cultures for Biological Teaching, Dr. Monica Taylor, 232
Army: the New, Science and, Col. E. H. Hills, 103; Prof. L. N. G. Filon, 133; Prof. R. Whiddington, 134; Lt.-Col. E. Gold; Dr. C. S. Myers, 135; Prof. A. R. Richardson, 170; K. E. Edgeworth, 233; C. S. Wright, 391; The Universities and the, Dr. F. J. M. Stratton, 234
Atomic: and Molecular Forces and Crystal Structure, Dr. A. E. Oxley, 327; and Molecular Structure, On, Dr. A. E. Oxley, 231; Structure, Theories of, I. Langmuir, 261; Weights, The Standard of, Prof. J. R. Partington, 264; Dr. S. Miall, 294
Atoms, On Langmuir's Theory of, S. C. Bradford, 41; Dr. A. E. Oxley, 105
Aurora of March 22-23, The, W. B. Housman, 200
Balloons, Free, The Stretching of Rubber in, Dr. H. P. Stevens; W. H. Dines, 613
Bees: and the Scarlet-Runner Bean, H. J. Lowe, 742; Eye-Colour in, Prof. T. D. A. Cockerell, 518
Bohr's Paramagnetic Hydrogen Atom, A Possible Cause for the Diamagnetism of, J. R. Ashworth, 516
Books, Scientific and Technical, Sir R. A. Gregory, 41
Brent Valley Bird Sanctuary, The, W. M. Webb, 614
British: and Foreign Scientific Apparatus, D. H. Baird, 390; J. W. Ogilvy, 424; J. S. Dunkerly, 425; F. W. Watson Baker, 518; Prof. W. M. Bayliss, 641; and Metric Systems of Weights and Measures, M. E. Yeatman, 355; A. S. E. Ackermann, 456
Buzzards and Bitterns, Rev. Canon E. McClure, 105
Calendar Reform, C. Flammarion; Dr. A. C. D. Crommelin, 105
Chemical Service, The Indian, Prof. Jocelyn Thorpe, 324; Sir Prafulla Chandra Rây, 325; Dr. M. W. Travers, 354
Chlorine: The Separation of the Element, into Normal Chlorine and Meta-Chlorine, and the Positive Electron, Prof. W. D. Harkins; Dr. F. W. Aston, 230; the Isotopes of, The Separation of, D. L. Chapman, 487, 611; Prof. F. Soddy, 516, 642; A. F. Core, 582, 677
Commercial Parasitism in the Cotton Industry, O. F. Cook, 548
Contour Colouring, the Layer System of, Dr. J. G. Bartholomew and, G. G. Chisholm, 328
Cotton: Growing in the British Empire, Dr. W. Lawrence Balls, 103; Sir George Watt, 104; Industry, Commercial Parasitism in the, O. F. Cook, 548
Cricket, The Mole, F. V. D., 294
Crystal Structure, Atomic and Molecular Forces and, Dr. A. E. Oxley, 327
Daylight Saving and the Length of the Working Day, Annie D. Betts, 41
Decimal Coinage, H. Allcock, 261
Definite Integrals between Finite Limits, A New Method for Approximate Evaluation of, A. F. Dufton, 354, 455; C. F. Merchant, 422; Commander T. Y. Baker, 486
Diamagnetism: and the Structure of the Hydrogen Molecule, Dr. A. E. Oxley, 581; of Bohr's Paramagnetic Hydrogen Atom, A Possible Cause for the, Dr. J. R. Ashworth, 516; of Hydrogen, The, Dr. J. R. Ashworth, 645; Dr. A. E. Oxley, 709
Doctor of Philosophy in England, The, Dr. H. O. Forbes, 234
Eiffel Tower Wireless Time-Signals, Prof. R. A. Sampson, 265
Elements, The Constitution of the, Dr. F. W. Aston, 8, 547
Ellipse, Perimeter of an, R. A. P. Rogers, 8
Entomologists, Practical, The Training of, Dr. A. D. Imms, 676
Eocene Flints, Naturally Fractured, J. Reid Moir, 358
Equivalence, The Principle of, and the Notion of Force, C. A. Richardson, 72
Expenses of Scientific Work, Major A. G. Church, 72
Fellow-Workers, Sir Ronald Ross, 455
Fireball of February 4, M. L. Dey, W. F. Denning, 105
Fishery Investigations, International Council for, X. Y. Z., 262; Prof. W. C. McIntosh, 167, 358
FitzGerald-Lorentz Contraction Theory, The, H. H. Poole, 200
Fizeau Effect in an Electron Stream, An Attempt to Detect the, Prof. R. Whiddington, 708
Flying-fish, The Flight of, Dr. J. McNamara, 421; Prof. W. N. F. Woodland, Sir David Wilson-Barker, 455
Genera and Species, A. Mallock, 675
Glacial Anticyclone, The Mechanics of the, illustrated by Experiment, Prof. W. H. Hobbs, 644
Gravitational: Deflection of High-speed Particles, Prof. A. S. Eddington, 37; H. G. Forder, 138; L. Page, 233; Shift of Spectral Lines, Dr. H. Jeffreys, 37
Halo, A Peculiar, Capt. C. J. P. Cave, 171
Hawthorn-Blossom, Early, Lady Jenny Rose, 234
High Levels in the Atmosphere, Attainment of, W. H. Dines, 454
High Rates of Ascent of Pilot Balloons, Dr. W. van Bemmelen, 485; J. S. Dines, 581
Hydrogen, The Secondary Spectrum of, Prof. J. W. Nicholson, 166
Hyperbolic Space, Relativity and, Prof. A. McAulay, 808
Ice, Curious Formation of, A. S. E. Ackermann, 741
Indian Chemical Service, The, Prof. Jocelyn Thorpe, 324; Sir Prafulla Chandra Rây, 325; Dr. M. W. Travers, 354
Industrial Research, Scientific Direction of, Major A. G. Church, 40
Integration, Approximate, and of Computing Areas, Some Methods of, A. S. Percival, 70; Prof. J. B. Dale; R. A. P. Rogers, 138
Ionisation in the Solar Chromosphere, M. N. Saha, 232
Isomerism, An Electronic Theory of, Dr. H. S. Allen, 71; W. E. Garner; S. C. Bradford, 171
Isotopes: The Separation of, Dr. T. R. Merton and Brig.-Gen. H. Hartley, 104; of Chlorine, The Separation of the, D. L. Chapman, 487, 611; Prof. F. Soddy, 516, 642; A. F. Core, 582, 677
Jupiter, The Great Red Spot on, W. F. Denning, 423
Kent's Cavern, The Condition of, E. A. Martin, 742
Knowledge and Power, L. Bairstow, 135; F. O. I., Dr. J. W. Evans, 165
Laboratory Fittings, The Cost of, A. E. Munby, 294, 456; C. Beck, 355; B. H. Morphy; C. Baker, 356; Bellingham and Stanley, Ltd., W. Taylor; H. W. Ashfield, 357
Langmuir's Theory of Atoms, On, S. C. Bradford, 41; Dr. A. E. Oxley, 105
Light: Deflection of, During a Solar Eclipse, J. A. Orange; Dr. A. C. D. Crommelin, 8; the Deflection of, Marat and, Prof. W. A. Osborne, 456
London University Site and Needs, Sir E. Sharpey Schafer, 484
Magnetic: Shell, The Construction of a, Equivalent to a given Electric Current, Dr. A. A. Robb, 199; Storm of March 22-23, The, and Associated Phenomena, Dr. C. Chree, 136; Rev. A. L. Cortie, 137; Dr. A. C. Mitchell, 170
Marat and the Deflection of Light, Prof. W. A. Osborne, 456
Medical Education, Science in, Prof. S. J. Hickson, 643

Mercury, Motion of, A Dynamical Specification of the, G. W. Walker, 198
Meteorological: Conditions of an Ice Cap, R. F. T. Granger, 709; Office, The Position of the, Dr. H. R. Mill, W. W. Bryant, 38
Migrations in the Sea, The Physiology of, Prof. A. Meek, 197
Mole Cricket, The, F. V. D., 294
Mortlakes as a Cause of River Windings, T. S. Ellis, 264; H. Bury, 391
Moseley Memorial, Sir Henry A. Miers, C. G. Darwin, and Dr. H. Robinson, 200
Muscular Efficiency, A. Mallock, 197
Museums and the State, Prof. E. W. MacBride, Prof. J. W. Gregory, 68; Dr. F. A. Bather, Dr. W. E. Hoyle, 69; W. G. Wagner, 70; Sir E. Ray Lankester, 100: Prof. J. Stanley Gardiner, 101; Dr. W. M. Tattersall, 102; F.R.S., 136
Musk Plants, Loss of Fragrance of, Hon. Col. C. J. Bond, 709
Officers, Seconding of, for Study at Universities, Prof. J. Wertheimer, 41
Organisation of Scientific Work, Dr. W. Bateson, J. S. Gamble, Sir Ronald Ross, 6; Dr. E. J. Russell, Prof. A. C. Seward, 7; Sir J. C. Bose, 39; Sir T. H. Middleton, 103; Sir Leonard Rogers, 292; in India, Sir Thomas H. Holland, 452
Ostrich, A Stalked Parapineal Vesicle in the, Prof. J. E. Duerden, 516
Ozone in the Atmosphere, Occurrence of, J. N. Pring, 645
Percussion Figures, Dr. B. G. Escher, 171
Pilot Balloons, High Rates of Ascent of, Dr. W. van Bemmelen, 485; J. S. Dines, 581
Pine, The Cluster, Dr. M. Grabham, 675
Plant Life in Cheddar Caves, L. Pendred, 709
Plumage Bill, The, and Bird Protection, Sir H. H. Johnston, Prof. H. M. Lefroy, 168; Sir Herbert Maxwell, Prof. A. Dendy, 169; Dr. W. E. Collinge, 196; Prof. J. E. Duerden, 263
Rainbow Inside Out, A, C. O. Bartrum, 388
Relativity: and Hyperbolic Space, Prof. A. McAulay, 808; and Reality, Prof. R. A. Sampson, 708
Royal Military Academy, The, J. Young, 486
Science: and Scholasticism, Prof. J. J. Walsh, 547; Dr. C. Singer, 548; and the New Army, Col. E. H. Hills, 103; Prof. L. N. G. Filon, 133; Prof. R. Whiddington, 134; Lt.-Col. E. Gold, Dr. C. S. Myers, 135; Prof. A. R. Richardson, 170; K. E. Edgeworth, 233; C. S. Wright, 391; in Medical Education, Prof. S. J. Hickson, 643
Scientific: and Technical Books, Sir R. A. Gregory, 41; Apparatus from Abroad, Prof. W. M. Bayliss, 293; C. Beck, 355; B. H. Morphy, C. Baker, 356; Bellingham and Stanley, Ltd., W. Taylor, H. W. Ashfield, 357; British and Foreign, D. H. Baird, 390; J. W. Ogilvy, 424; J. S. Dunkerly, 425; F. W. Watson Baker, 518; Prof. W. M. Bayliss, 641; Direction of Industrial Research, Major A. G. Church, 40; Publications, The Cost of, Prof. W. A. Herdman, Prof. H. H. Turner, 326; E. B. Knobel, W. W. Bryant, 327; Prof. G. H. Hardy, Dr. A. B. Rendle, 353; Dr. B. Daydon Jackson, Dr. C. S. Myers, 354; Dr. C. G. Knott, 425; Research, Dr. J. W. Evans, 358; Reunions at the Natural History Museum, Dr. G. F. H. Smith, 72; Work, Expenses of, Major A. G. Church, 72; Its Spirit and Reward, Dr. G. J. Fowler, 387; Organisation of, Dr. W. Bateson, J. S. Gamble, Sir Ronald Ross, 6; Dr. E. J. Russell, Prof. A. C. Seward, 7; Sir J. C. Bose, 39; Sir T. H. Middleton, 103; Sir Leonard Rogers, 292; in India, Sir Thomas H. Holland, 452
Sea and Sky at Sunset, Lt.-Col. K. E. Edgeworth, J. S. D., 358
Spectrum, An Experiment on the, Dr. R. A. Houstoun, 421
Sphexapata (*Miltogramma*) *conica*, Note on the Habits of the Tachinid Fly, O. H Latter, 614
Spores and Plant Life in Deep Caves, The Carrying Power of, E. A. Stoney, 740
Sumner Lines in Navigation, Use of, Prof. G. C. Comstock, Capt. T. H. Tizard, 742; Dr. J. Ball, 806
Telephotography, A Note on, A. B., 488
Temperature Variations at 10,000 ft., C. K. M. Douglas, 614
Thrush, The First Act of a Young, Honor M. M. Perrycoste, 456
Trichodynamics, Dr. W. Lawrence Balls, 777
Universities, The, and the Army, Dr. F. J. M. Stratton, 234
University: Grants, Sir Michael E. Sadler, 740; Principal C. Grant Robertson, 774; Prof. W. H. Perkin, 805; Stipends and Pensions, Prof. G. W. O. Howe, 582
Vapour Densities, Calculation of, R. G. Durrant, 742
Vocal Notes, Seven, Photographs of, Dr. W. Perrett, 39
Volcanic Rocks in the Anglo-Egyptian Sudan, Dr. G. W. Grabham, 199
Waage's Photochemical Synthesis of Phloroglucin from Glucose, Dr. M. Nierenstein, 391
Wasps, W. F. Denning, 328
Waves, Growth of, A. Mallock, 777
Weather Forecasts and Meteorology, A. Mallock, 580
Weights and Measures, British and Metric Systems of, M. E. Yeatman, 355; A. S. E. Ackermann, 456
Wireless: Station for Astronomy, Central, Major W. J. S. Lockyer, 454; Time-Signals, Eiffel Tower, Prof. R. A. Sampson, 265

Corrosion Research Committee, Appeal for Funds by the, 304
Cosmogony, Problems of, and Stellar Dynamics, J. H. Jeans, 31
Cottage Building, Experimental, 792
Cotton: Climates of the British Empire suitable for the Cultivation of, C. E. P. Brooks, 338; Egyptian, Researches on, Dr. W. L. Balls, 664
Cotton Growing: Future Organisation, 793; in South America, Possibilities of, G. McC. McBride, 399; in the British Empire, Dr. W. Lawrence Balls, 103; Sir George Watt, 104; Industry, Commercial Parasitism in the, O. F. Cook, 548; Research, 840; Pests, H. H., 503
Cotunnite, Anglesite, Leadhillite, and Galena, The Occurrence of, on Fused Lead from the Wreck of the Fireship *Firebrand*, Falmouth Harbour, A. Russell, 156
Coumarin, *Melettis melissophyllum*, A New Plant containing, P. Guérin and A. Goris, 411
"Cresineol," T. T. Cocking, 726
Crete, Excavations in, M. Xanthoudides, 273
Cricket, The Mole, F. V. D., 294
Crocker Land Expedition, Mollusca obtained by the, F. C. Baker, 593
Crookes Radiometer, A Modified Theory of the, G. D. West, 473
Crop Production, British, Dr. E. J. Russell, 176, 206
Crystal Structure: Atomic and Molecular Forces and, Dr. A. E. Oxley, 327; Prof. W. L. Bragg, 646
Cubic Curves, Construction of the Ninth Intersection of two, passing through eight given Coplanar Points, Prof. H. F. Baker, 474
Cuckoo's Egg, The Story of a, Hilda Terras, 746
Cumacea and Phyllocarida obtained by the Ingolf and other expeditions, Dr. H. J. Hansen, 81
Currency Reform and the Need for a Nickel Coinage on a Decimal Basis, 114
"Cyanogen" Bands, The Origin of the, S. Barratt, 633
Cylindrical Octosection, On, W. Burnside, 473
Cyprus: The Agricultural Industries of, W. Bevan, 757; The Handbook of, Eighth Issue, Edited by H. C. Luke and D. J. Jardine, 291
Cytology: An Introduction to the Study of, Prof. L. Doncaster, 190; English, 190; The Modern Technique of, J. B. Gatenby, 463; with special reference to the Metazoan Nucleus, Prof. W. E. Agar, 482

Dacca University: P. J. Hartog appointed Vice-Chancellor, 509
Dante and Trepidation, O. Z. Bianco, 664
Day Continuation Schools, H. J. Taylor, 23
Daylight Saving and the Length of the Working Day, Annie D. Betts, 41

DEATHS.

Allen (Sir Charles), 239
Backhouse (T. W.), 335
Bartholomew (Dr. J. G.), 238
Bell (A. J. M.), 721
Brashear (Dr. J. A.), 273
Brindley (H. S. B.), 208
Burrows (Principal R. M.), 364
Carnot (A.), 555
Chalmers (Dr. A. J.), 271
Creak (Capt. E. W.), 178; 300
De Candolle (A. P.), 365
Doncaster (Prof. L.), 431; 461
Drysdale (J. W. W.), 590
Eisig (Prof. H.), 50
Failes (Rev. W.), 18
Fullarton (Dr. J. H.), 365
Gayley (J.), 239
Gorgas (Major-Gen. W. C.), 590; 620
Guthrie (Lord), 302
Guyon (Prof. J. C. F.), 721
Hall (Maxwell), 302
Heenan (H.), 555
Herkless (Ppl. Sir John), 495
Hewitt (Dr. C. Gordon), 18; 75
Hind (Dr. Wheelton), 555
Hiorns (A. H.), 335
Huntington (Prof. A. K.), 239; 271
Hyatt (J. W.), 462
Hyslop (Dr. J. H.), 555
Inostranseff (Prof. A. A.), 525
Kennedy (J.), 555
Kinch (Prof. E.), 784
Kirkaldy (J.), 784
Lapworth (Prof. C.), 76; 110
Leslie (C. D.), 19
Lockyer (Sir Norman), 781; 784; 831
Loder (Sir Edmund Giles), 301
Lyster (A. G.), 143
MacArthur (J. S.), 112
Maclaurin (Dr R. C.), 144
McClelland (Prof. J. A.), 238
Messel (Dr. R.), 239; 270
Metcalfe (J.), 273
Morant (Sir Robert), 76
Moreno (Dr. F. P.), 76
Morrison (Dr. G. E.), 431
Moses (Prof. A. J.), 365
Munro (Dr. R.), 685
Nordenfelt (T.), 19
O'Shea (Prof. L. T.), 239; 272
Palander (Admiral A. L.), 754
Perry (Prof. John), 751; 752
Pfeffer (Prof. W.), 302
Poincaré (L.), 50; 208
Pott (J. A.), 334
Priest (F. E.), 273
Procter (J.), 112
Pryor (M. R.), 333

Ramanujan (Prof. S.), 431; 494
Rawnsley (Canon H D.), 430
Reynolds (Prof. J. Emerson), 49
Rhodes (C. E.), 405
Righi (Prof. A.), 462; 753
Russell (Sir Thomas W.), 302
Rydberg (Prof. J. R.), 525
Saccardo (Dr. P. A.), 76
Sheldon (W.), 405
Starkie (Dr. W. J. M.), 686
Stewardson (H. C.), 302
Stuart (Sir Thomas P. Anderson), 111
Tarleton (Dr. F. A.), 525; 554
Taylor (Sedley), 143
Timiriazeff (Prof. C. A.), 430
Treub (Prof. H.), 208
Ussher (W. A. E.), 144
Vail (T. N.), 272
West (Dr. S. H.), 50
Williams (W. R.), 76
Wimmer (Prof. L. F. A.), 365
Worsdell (W.), 239

Decimal Coinage: H. Allcock, 261; Report of the Royal Commission on, 145, 210
Definite Integrals: A New Method for Approximate Evaluation of, between Finite Limits, A. F. Dufton, 354, 455; Commander T. Y. Baker, 486; C. F. Merchant, 422
Denmark, Plant Culture in, Prof. J. K. Ravn, 701
Denning's Comet of 1881 and A Meteoric Shower, 500
Dental Cements, The Setting of, Dr. T. M. Lowry and S. Wilding, 217
Deutsche Seewarte, Report of the, for 1914-18, 528
Devonian of Ferques (Lower Boulonnais), The, J W D. Robinson, 314
Diabetes, Returns concerning, 723
Dialkyl*cyclo*hexanones, The Constitution of Some, R Cornubert, 475
Diamagnetism: and the Structure of the Hydrogen Molecule, Dr. A. E. Oxley, 581; of Bohr's Paramagnetic Hydrogen Atom, A Possible Cause for the, J. R. Ashworth, 516; of Hydrogen, The, J. R. Ashworth, 645; Dr. A. E. Oxley, 709
Diamond, Overgrowths on, J. R. Sutton, 507
Diatoms on the Skin of Whales, Occurrence of, A. G. Bennett and E. W. Nelson, 633
Diazo-compounds: New Catalytic Elements for the Transformation of, A. Korczynski, W. Mrozinski, and W. Vielau, 763; The Chemistry and Technology of the, Dr. J. C. Cain, second edition, 449
Dielectric of Commercial Cables, Loss of Energy in the, M. Rennesson, 218
Diesel Engine, Marine, The Running and Maintenance of the, J. Lamb, 290
Differential Equations: Graphical Treatment of, Dr. S. Brodetsky, 466; Solutions of the Examples in a Treatise on, Prof. A. R Forsyth, 260
Diffraction: Grating, Experiments with a Plane, using Convergent Light, G. F. C. Searle, 174; Image of a Disc, H. Nagaoka, 436
Diffusion through a Rubber Membrane, The Process of, H. A. Daynes, 122
Digestive Hœmoclasia: and Latent Hepatism, The Proof of, F. Widal, P. Abrami, and N. Iancovesco, 704; in the Study of Hepatic Insufficiency, Proof of, F. Widal, P. Abrami and N. Iancovesco, 762; Hydrolyses by Mechanical Ionisation of Water, J. E. Abelous and J. Aloy, 380
Dimethyl*cyclo*hexanone, The Constitution of the, obtained by Methylation of the Sodium derivative of *o*-Methyl-*cyclo*hexanone, A. Haller and R. Cornubert, 250
Dimetrodon, a Skeleton of, from the Permian of Texas, C. W. Gilmore, 118
Dioptric Instruments, Theory of, 542
Discovery, The Encouragement of, 189
Disease, Radiological Diagnosis of, 4
Distillation in Steam, Some Applications of the Method of, Dr. J. Reilly and W. J. Hickinbottom, 379
Doctor of Philosophy in England, The, 204; Dr H O Forbes, 234
Dogs, Vivisection of, The Bill to Prohibit the, 51 112
Dominion Astrophysical Observatory, Victoria, B C., Publications of the, Vol. I, No 1, 658
Donnybrook Fair, R J. Kelly, 433
Dove Marine Laboratory, Report of the, 216
Drosophila: Genetic Studies of, Prof. L. Doncaster, 405; *melanogaster*, Contributions to the Genetics of Prof. T. H. Morgan· Dr. C. B. Bridges; A. H. Sturtevant, 405
Dublin: Trinity College, Forthcoming Election to a Fellowship in Experimental Physics or Physical Chemistry, 731; University, decision to grant Honorary Degrees to Dr. W. Crooke, Lord Bryce, Sir Donald MacAlister, Sir Archibald E. Garrod, Prof. W. H. Bragg, and Prof R. A. Millikan, 89; and Trinity College, Dublin, appointment of a Royal Commission to inquire into the financial resources and working of, 89
Duplex Wireless Telephony, Application of, to Aircraft, Capt. P. P. Eckersley, 154

Dutch East Indies, Rainfall Records in the, for 1915, 1916, 1917, 368
Dye Industry: Development of the Synthetic, V. Clay, 686; Present State of the, 413
Dyes, The Manufacture of Intermediate Products for, Dr. J. C. Cain, second edition, 260
Dynamics: Graphic, Elements of, E. S. Andrews, 65; The Fundamental Equations of Dynamics and its Main Co-ordinate Systems Vectorially Treated and Illustrated from Rigid Dynamics, Prof. F. Slate, 65

Earth: The Absorptive Power of, for Manganese, P. Nottin, 666; The Elasticity of the, Earthquake Waves and, Dr. C. G. Knott, 730
Earthquake Waves and the Elasticity of the Earth, Dr. C. G. Knott, 730
Earthquakes in Italy in 1896 to 1914, The Frequency of, R. D. Oldham, 186
Earth's Magnetic Field, The Daily Variations of the, Miss A. van Vleuten, 401
Earthworks and Retaining Walls, P. M. Crosthwaite, 87; A. R. Fulton, 88
Easter, The Date of, 691
Easter Island, The Mystery of, the Story of an Expedition, Mrs. Scoresby Routledge, 583
Eastern Europe: Health Conditions in, Typhus a Serious Menace, Dr. N. White, 723
Economic: Biologists, Association of, Meeting of the, 170; Entomologists, The Education of, Prof. H. Maxwell Lefroy, and others, 503
Edinburgh University: Sir George Watt to deliver the course of lectures on Indian Forest Trees; J. Templeton appointed Lecturer in Botany; Dr. Bella D. MacCallum appointed assistant in the Botany department; a series of lectures on Aeronautics to be delivered, 120; l'Abbé Breuil appointed Munro Lecturer on Prehistoric Archæology for 1920-21, 121; The King to lay the foundation stone of new buildings; no person not of British nationality and parentage to be appointed professor of German; Dr. G. L. Malcolm Smith appointed assistant in Clinical Medicine; J. Anderson appointed Lecturer in Logic and Metaphysics; Mesozoic fossil plants presented to the Geological Department by Dr. R. Kidston; loans of forestry exhibits to the Forestry Department, 280; E. P. Stebbing appointed Professor of Forestry; J. P. Dunn a Lecturer in the Department of Music; bequest by Dr. J. G. Bartholomew, 537; Foundation-stone of new buildings laid by the King; acceptance of the Honorary Degree of LL.D. by the Queen, 601; The New Science Buildings of, 627
Education: and Science in the Civil Service Estimates for 1920-21, 246; Act of 1918, Working of the, Marquess of Crewe, 22; L.C.C. Draft Scheme, 693; A National System of, 345; J. C. M. Garnett, 728; in the New Era, Prof. F. Soddy, 561; Medical, 573; Medical Science and, Sir T. Clifford Allbutt, and others, 661; National, 213; Naval, 445; Popular, since the Act of 1870, Miss J. F. Wood, 213; The Relationship of, to Research in Aeronautics, 14; University and Higher Technical, 509
Educational Systems, The Evil in Existing, F. W. Sanderson, 561
Eel Fisheries, Report on, 368
Egypt: Discovery of a Remarkable Ebony Statue in, Prof. Flinders Petrie, 463; the Birds of, Hand-list of, M. J. Nicoll, 674; Upper, Personal Ornaments found in, Prof. Flinders Petrie and Dr. Dennison, 210
Egyptian Cotton, Researches on, Dr. W. L. Balls, 664
Eiffel Tower Wireless Time-Signals, Prof. R. A. Sampson, 265
Einstein: Deflecton of Light, The, Dr. A. C. D. Crommelin; Prof. C. V. Raman, 23; Displacement of Spectral Lines, The, J. Evershed and C. E. St. John, 244; Theory, The, Prof. E. P. Adams, 842; The Foundations of, Dr. E. Freundlich, translated by H. L. Brose, 350; Relativity, Prof. A. Eddington, and others, 306
Elasticity, the Mathematical Theory of, A Treatise on, Prof. A. E. H. Love, third edition, 511
Electric Charge on Rain, The, Prof. J. A. McClelland and A. Gilmour, 498; Conductors, Calculation of, W. T. Taylor, 229; Currents in Telephone and Telegraph Conductors, The Propagation of, Prof. J. A. Fleming, third edition, 611; Furnace in Great Britain, Recent Developments of the, D. F. Campbell, 695; Railway Contact Systems, Sir Philip Dawson, 657
Electrical and Allied Industries, Education and Training for the, 151; Anemometer, A New, E. Rothé, 443; Conductivity, Measurement of, in Metals and Alloys at High Temperatures, J. L. Haughton, 602; Energy, The Transport of, to great distances, E. Brylinski, 347; Engineering and their Application, The Principles of, Prof. G. Kapp, Vol. II., Application, 418; Examples in, J. F. Gill and F. J. Teago, 195; Oscillations in Water, The Propagation of Sustained, and the Dielectric Constant of Water, M. Sauzin, 763
Electricity: Applications of, Dr. A. Russell, 418; Conduction of, through fused Sodium Hydrate, Dr. A. Fleck and T. Wallace, 602; Distribution in France, Maps of the Network of, A. Rateau, 571; Its Production and Applications, R. E. Neale, 804
Electro: -chemical Chlorate, Theory of, and Perchlorate formation, N. V. S. Knibbs and H. Palfreeman, 602; deposition of Metals, Uses of the, W. E. Hughes, 339
Electrolytes, Colloidal, Prof. J. W. McBain, 960
Electrolytic: Dissociation, Influence of, on the Distillation Steam of the Volatile Fatty Acids, Dr. J. Reilly and W. J. Hickinbottom, 379; Iron, The Annealing of, J. Cournot, 763; Resistances, Measurement of, using Alternating Currents, Dr. H. F. Haworth, 602
Electrometer, An Absolute Bispherical, A. Guillet and M. Aubert, 59
Electron: Collisions, Effects of, with Atmospheric Neon, Dr. F. Horton and Ann C. Davies, 633; Emission from Hot Bodies, The, Sih Ling Ting, 441
Electro-therapy, The History of, Dr. W. J. Turrell, 81
Elements: The Constitution of the, Dr. F. W. Aston, 8, 547; The Origin of the, Dr. J. H. Vincent, 842
Elgie's Weather Book: For the General Reader, J. H. Elgie, 739
Ellipse, Perimeter of an, R. A. P. Rogers, 8
Empire Timber Exhibition, The, A. L. Howard, 691
Employment Psychology: The Application of Scientific Methods to the Selection, Training, and Grading of Employees, Dr. H. C. Link, 673
Encephalitis Lethargica: Dr. Reece and Dr. MacNalty, 151; in Karachi, Capts. Malone and Maitra, 834
Engineering: Descriptive Geometry and Drawing, Capt. F. W. Bartlett and Prof. T. W. Johnson, 3 Parts, 515; Education: Essays for English, selected and edited by Prof. R. P. Baker, 258; Naval, Progress in, Vice-Admiral Sir George Goodwin, 235; Research in the United States, A. P. M. Fleming, 598; Science and, 258
Engineers, Education of, 152
English: Magic and Medicine, Early, Dr. C. Singer, 337 Sedimentary Series, Thickness of, G. W. Lamplugh, 338; Skeleton, A Study of the Long Bones of the, Prof. Karl Pearson and Julia Bell. Part I, The Femur. Part I, Section II, The Femur of Man, with special reference to other Primate Femora, 767
Engrais: Amendements Produits Anticryptogamiques et Insecticides, Dr. E. Demoussy, 738
Entomological: Conference, The, 502; -Meteorological Records of Geological Facts in the Life of British Lepidoptera Major H. C. Gunton, 26
Entomologists, Practical, The Training of, Dr. A. D. Imms, 676
Entomology, Economic, in the Philippines, 600
Eocene Flints, Naturally Fractured, J. Reid Moir, 358
"Eolith" Factory, A Natural, beneath the Thanet Sand, S. H. Warren, 378
Equilibrium Constant, The Pressure Variation of, in Dilute Solution, Dr. A. M. Williams, 603
Equivalence, The Principle of, and the Notion of Force, C. A. Richardson, 72
θ Eridani, The Binary Star, B. H. Dawson, 84
Errors, The Balancing of, T. Smith, 122
Eruption of Katla (Iceland) in 1918, The, A. Lacroix, 314
Ether: -Air Mixtures, The Self-Ignition of, the Causes of,

the late Prof. McClelland and Rev. H. V. Gill, 634; Differential Radiometer, The, W. H. Dines, 570; Oxides, The Catalytic Formation of, A. Mailhe and F. de Godon, 27; The Equation of State of, E. Ariès, 314; The Critical State of, M. Audant, 634
Ethylene Sulphide, C_2H_4S, M. Delépine, 666
Eucalyptus Oils, The Manufacture of Thymol, Menthone, and Menthol from, H. G. Smith and A. R. Penfold, 732
Euclid in Greek. Book I, with introduction and notes, Sir Thomas L. Heath, 288
Euclid's Elements, 288
Eugenics, Civics, and Ethcs, Sir Charles Walston, 804
European Thought, Recent Developments in, Essays arranged and edited by F. S. Marvin, 607
Evelyn, Pepys, and Swift, Weather Notes of, in Relation to British Climate, Capt C. J. P. Cave, 393
Evolution, The Method of, Prof. E. W. MacBride, 655
Exeter University College, Prof. H. J. W. Hetherington appointed Principal of, 280
Exhibition of Diseases of the Para Rubber Tree, 86
Expansion caused by Joule's Effect at the Contact of Two Solids, The, J. Fallou, 506
Exploration of the Sea, International Council for the: Meeting of the, 51, 84; H. G. Maurice elected President of the, 86
Explosive Sounds, The Velocity of, Prof. D. C. Miller, 842
Eyam Moor Circle in Derbyshire, Map of the, J. S. Wilson and G. A. Garfitt, 180
Eye-Colour in Bees, Prof. T. D. A. Cockerell, 518

Falkland Islands and South Georgia, The Climate and Weather of, C. E. P. Brooks, 275
Falmouth Observatory, The Weather Experienced at, 656
Farm Animals, Physiology of, T. B. Wood and Dr. F. H. A. Marshall. Part I, General, Dr. F. H. A. Marshall, 704
February, The Weather of, 53
Federation of Science, The, 317
Feelings, A Natural History of the, 3
Felichthys felis, The Ovary of, E. W. Gudger, 279
Fellow-Workers, Sir Ronald Ross, 455
Felsted School Scientific Society, Report of the, for 1918 and 1919, 623
Fertilisers, Artificial, The Manufacture of, Dr. E. J. Russell, 4
Fertilising Materials, Mining and Manufacture of, and their Relation to Soils, S. L. Lloyd, 4
Fertility of the Social Classes in England and Wales, The, Dr. T. H. C. Stevenson, 655
Fertilization, Problems of, Prof. F. R. Lillie, 225
Ferraris' "Dioptric Instruments": Being an Elementary Exposition of Gauss' Theory and its Applications. Translated by Dr. O. Faber from Prof. F. Lippich's German translation of Prof. G. Ferraris' "The Fundamental Properties of Dioptric Instruments," 542
Ferrous Industries during the past fifty years, The Progress made in the, Dr. J. E. Stead, 403
Fevers in the Tropics, Sir Leonard Rogers, Third edition, 33
Field: Glasses, Monocular and Binocular, Report on, E. P. Hyde, P. W. Cobb, H. M. Johnson and W. Weniger, 243; Museum of Natural History, Work of the Botanical Laboratories of the, 408
Filter Press, Recessed Plate and Plate-and-Frame Types of, E. A. Alliott, 696
Filtration, Centrifugal, A New Process for, W. J. Gee, 696
Finland, Standard Time in, H. R. 145
Finnic Question, The, and Some Baltic Problems, H. Peake, 723
Fireball: A Bright, 370; of February 4, M. L. Dey; W. F. Denning, 105
Fisheries, Department of the Ministry of Agriculture and Fisheries, Prof. J. Stanley Gardiner to direct temporarily the scientific work of the, 52
Fishery: Investigations, Ser. III, Hydrography. Vol. I, The English Channel, Part II; Vol. II, Lightship Observations, Part I; Vol. III, The Atlantic Ocean, Part I, Dr. E. C. Jee, 150; International, 84; Council for, Prof. W. C. McIntosh, 167, 358; X.Y.Z., 262; Recent, 216
Fishes, Determination of the Age of, by Inspection of the Scales, R. E. Savage, Rosa M. Lee, 275
Fish-Food in the Limfjord, 1909-1917, P. B. Jensen, 527
Fishing, "Intensive," Drs. A. C. Johansen and Kirstine, 216
FitzGerald-Lorentz Contraction Theory, The, H. H. Poole, 200
Fizeau Effect in an Electron Stream, An Attempt to detect the, Prof R. Whiddington, 708
Flame in Complex Gaseous Mixtures, The Propagation of, W. Payman, 279
Flight at High Altitudes, J. Villey, 346
Flint Implements, The Earliest, 289
Flints: Trimming of, in Algeria, M. W. Hilton-Simpson, 81; worked, with finger-grips, Miss Nina F. Layard, 557
Flora: Land, The Earliest Known, Prof. F. O. Bower, 681, 712; of Jamaica. Vol. IV., Dicotyledons: Families Leguminosæ to Callitrichaceæ, W. Fawcett and Dr. A. B. Rendle, 738; of the Hawaiian Islands, 217; of the Presidency of Madras, J. S. Gamble, Part III, 36
Flowers: Wild, Australian, Second Series, photographed by, A. E. Sulman, 34; Wild, of New South Wales, A Popular Guide to the, F. Sulman, Vol. II, 34; Wild, Some Familiar, Photographed by A. E. Sulman, 34
Fluid in Turbulent Motion, The Conditions at the Boundary of a. T. E. Stanton, Miss D. Marshall and Mrs. C. N. Bryant, 441
Flying: at High Altitudes, The Physiological Aspect of, Dr. Guglielminetti, 401; -fish, The Flight of, Dr. J. McNamara, 421; Prof. W. N. F. Woodland; Sir David Wilson-Barker, 454
Fogs in the Eastern Sahara, Frequency of, J. Tilho, 571
Food: Consumption, National, in the United States, Prof. R. Pearl, 597; Inspectors of, Work of, Dr. MacFadden, 151; Its Composition and Preparation, Mary T. Dowd and Jean D. Jameson, 99; Science of, 99; Supplies in Peace and War, Sir R. Henry Raw, 320; Supply, The National, 371; The Nation's, Dr. E. J. Russell, 320; Want of, and the Chemical Composition of Milk, Ch. Porcher, 571
Foods, Bacteriology and Mycology of, Dr. F. W. Tanner, 99
Foraminifera from off New Zealand, Recent, J. A. Cushman, 242
Foreign Decorations, permission to scientific men to wear, 463
Forest Research, 639
Forestry: Commercial, in Britain; Its Decline and Revival, E. P. Stebbing, 577; Commission, The, 215; Conference, The British Empire, 759; Tree Diseases, and Timber, 577
Forests: Our National, A Short Popular Account of the Work of the U.S. Forest Service on the National Forests, Dr. R. H. D. Boerker, 577; Woods, and Trees in Relation to Hygiene, Prof. A. Henry, 158
Forficula auricularia, The Food-Plants of, H. H. Brindley, 378
Formal and Chromium Compounds as Fixing Agents, The Use of Mixtures of, E. Licent, 604
Formosa: The Flora of the Island of, B. Hayata, 664; The Rainfall in the Island of, 680
Fossil: -bearing Layer in the Flanders Clay at Watten (Nord), Discovery of a, G. Dubois, 705; Plants: A Textbook for Students of Botany and Geology, Prof. A. C. Seward, Vol. IV, Ginkgoales, Coniferales, Gnetales, 97
Fossils: from the Miura Peninsula and its Immediate North, Prof. M. Yokoyama, 836; Lower Palæozoic, The Gray Collection of, to be purchased by the British Museum, (Natural History), 336; Old Age and Extinction in, Dr. W. D. Lang, 212
Fourth Gospel, The Beginning of the, Prof. P. Haupt, 764
France, Études sur le Climat de la, Deux. Partie, A. Angot, 119
Franklin Medals of the Franklin Institute presented to the Hon. Sir Charles A. Parsons and Prof. Svante A. Arrhenius, 432

Free Balloons, The Stretching of Rubber in, Dr. H. P. Stevens; W. H. Dines, 613
French Academy of Sciences, Sir James Dewar elected a Corresponding Member of the, 80; Sir Joseph Larmor elected a Corresponding Member of the, 113
French: Indo-China, The Reorganisation and Extension of the Scientific Services in, A. Chevalier, 401; Text-books of Chemistry, 63
Fruit Culture, Hardy, The Elements of, 545
Fruits, Wild, and How to Know Them, Dr. S. C. Johnson, 774
Fuel: Problems, 609; Production and Utilization, Dr. H. S. Taylor, 609; Research, Prof. J. W. Cobb, 550; The Conservation of, Sir Dugald Clerk, 406; Water, and Gas Analysis for Steam Users, J. B. C. Kershaw. Second edition, 227
Fumes of Ammonium Chloride in the Electric Field, The Double Refraction and Dichroism of the, S. Procopin, 571
Functional Relation of One Variable to each of a number of Correlated Variables, G. F. McEwen and E. L. Michael, 82
Fungal Diseases of the Common Larch, The, W. E. Hiley, 639

Gabbros of East Sooke, The, H. C. Cooke, 464
Galactic Condensation, R. T. A. Innes, 759
Galanthus nivalis, Inhibition of Invertase in the Sap of, T. G. Mason, 123
Gammarus chevreuxi, Experiments with, Dr. E. J. Allen and E. W. Sexton, 368
Garden, A, in the Dunes, 322
Gardening and Food Production, Sir Daniel Hall, 371
Gardens and Allotments, Social and Hygienic Conditions respecting, Sir Daniel Hall, 371
Gas Cylinders, Tests of, 113
Gases, The Molecular Energy in, Sir Alfred Ewing, 472
Gault and Cenomanian Strata, A Mass of, inverted on Lower Greensand, F. L. Kitchin and J. Pringle, 836
Gelatine Photographic Plates under Tropical Conditions, Working, A. P. Agnew, 182
γ Geminorum, The Duplicity of, Dr. Bernewitz, 340
Genera: and Species, A. Mallock, 675; The Persistence of, Dr. C. D. Walcott, 680
Genetic: Segregation, Dr. W. Bateson, 531; Studies of Drosophila, Prof. L. Doncaster, 405
Geodetic Survey in North America, 141
Geography: of Asia, A, J. Martin, 35; of Plants, The, Dr. M. E. Hardy, 386; Plea for a Wider Outlook in, Lt.-Col. Sir Francis Younghusband, 465
Geological: Society, Election of Officers and Council of the, R. D. Oldham, President, 52; Structure, Magnetic Disturbances and, 175; Survey and Museum, Dr. J. S. Flett appointed Director of the, 590; Survey Board, Appointment of a, 209
Géologie," "Les Grands Énigmes de la, Prof. P. Termier, 503
Geologische Reichsanstalt, Vienna, change of name to *Geologische Staatsanstalt*, and changes on the staff, 836
Geology: of the Mid-Continent Oilfields, Kansas, Oklahoma, and North Texas, Dr. T. O. Bosworth, 608; of the West Indies, The, 24
Geometry: Complex Elements in, Prof. G. B. Mathews, 736; Differential, The Elementary, of Plane Curves, R. H. Fowler, 321; Relativity and, E. Cunningham, 350; The Analytical, of the Straight Line and the Circle, J. Milne, 65; The Theory of the Imaginary in, together with the Trigonometry of the Imaginary, Prof. J. L. S. Hatton, 736
Geophysical Observations during the Solar Eclipse of May 29, 1919, Results of, Dr. L. A. Bauer, 842
Geotropic Response in Roots and Stems, The Chemical Reversal of, Prof. J. Small, 249
Gerhardt, Charles, Monument to, Sir T. E. Thorpe, 436
German: Aniline Dye Manufacturers, The German Government and the Combine of the, Dr. H. Levinstein, 722; Gas Warfare, The French Experience of, M. Florentin, 434; Imperial Chemicotechnical Test Laboratory, A Suggested, 785; Rhineland, The Chemical Industries of, 253
Germany, The Works Council Bill in, 145
Geum urbanum × *G. rivale*, The Stability and Fertility of the Hybrid, L. Blaringhem, 475
Gifford Lectures, Prof. Alexander's, Viscount Haldane, 798
Glacial Anticyclone, The Mechanics of the, illustrated by Experiment, Prof. W. H. Hobbs, 644
Glaciation of the South Downs, The, E. A. Martin, 530
Gland-cells of Internal Secretion in the Spinal Cord of the Skates, C. C. Speidel, 279
Glasgow: Health Department, Dr. A. K. Chalmers appointed Head of the Enlarged, 19; Royal Technical College, Dr. J. H. Andrew appointed Professor of Metallurgy at the, 249; Work of the, in the War, 410; W. M. Cumming appointed Senior Lecturer in Organic Chemistry at the, 630; R. S. Glennie appointed Chief Lecturer in Pharmaceutics at the, 841; University, Reports on the Hunterian Collections for 1918-19, 146; Conferment of Degrees upon P. A. Hillhouse, D. B. Meek, Dr. J. MacIntyre, and Sir Robert W. Philip; Award of Prizes, 568; Conferment of Degrees, 665; Dr. A. J. Ballantyne appointed Lecturer in Ophthalmology, 761.
Glass: Industry in the United States, Scientific Research and the, Dr. M. W. Travers, 9; -making, Principles of, 128; Manufacture, Dr. W. Rosenhain, Second Edition, 128; Research Association, The Appointment of a Director of Research to the, F. D. Acland and H. A. L. Fisher, 178; -ware, English Chemical, Wood Bros.' Catalogue of, 435; Scientific, Volumetric Testing of, 120
Globular Clusters and Spiral Nebulæ, The Parallaxes of, K. Lundmark, 215
Glossina Palpalis, Bionomics of, Dr. G. D. H. Carpenter, 663
Gloucestershire, The Ancient Entrenchments and Camps of, E. J. Burrow, 128
Glucosane, A. Pictet and P. Castan, 795
Glucose: Action of Hydrocyanic Acid on, Kiliani's Reaction, J. Bougault and J. Perrier, 443; in Plants, The Detection and Characterisation of, by a New Biochemical Method, Em. Bourquelot and M. Bridel, 218
Glue, Manufacture of, in the Tropics from Tannery Refuse, 690
Gobies, Our (Globiidæ) from the Egg to the Adult Stages, Prof. C. G. J. Petersen, 527
Gold: and Pearls in Neolithic Times, The Search for, W. J. Perry, 250; Deposition in the Bendigo Goldfield, The Factors Influencing, Dr. F. L. Stillwell, 465; Its Place in the Economy of Mankind, B. White, 774; Objects, Ancient, Found in an Irish Bog, E. C. R. Armstrong, 527
Golgi Apparatus, Method for the Demonstration of the, in Nervous and other Tissues, C. Da Fano, 249
Gonidia, Stages in the Sporulation of, within the Thallus of *Evernia prunastri*, Ach., R. Paulson, 281
Graduated Instruments for Volumetric Analysis, Gallenkamp and Co.'s List of, 306
Grain Pests, The Investigation of, Dr. A. D. Imms, 236
Grand Fleet, The, 1914-16, Lord Jellicoe, 93
Graphs, The Use of, in Society and Museum Statistics, H. St. George Gray, 463
Grasses and Rushes and How to Identify Them, J. H. Crabtree, 805
Grassland, The Improvement of, Dr. W. E. Brenchley, 408
Gravitation, Q. Majorana, VI., 251; Q. Majorana, 283; Q. Majorana, IX., 844; Einstein's Theory of, The Foundations of, Dr. E. Freundlich, Translated by H. L. Brose, 350
Gravitational Deflection of High-speed Particles, Prof. A. S. Eddington, 37; H. G. Forder, 138; L. Page, 233; Shift of Spectral Lines, Dr. H. Jeffreys, 37
Greek: at Oxford University, Abolition of Compulsory, 17; Science and Philosophy, Dr. C. Singer, 373
Greenwich: Royal Observatory, Annual Visitation of the, 469; Time or the Nearest Standard Meridian Time for Magnetic Records? Dr. L. A. Bauer, 21

Groningen Astronomical Laboratory, Publications of the, No. 29, Prof. J. C. Kapteyn, 838
Ground-squirrels of California, The, J. Grinnell and J. Dixon, 81
Gunnery, Meteorology in, The Importance of, Dr. E. M. Wedderburn, 492
Guthrie Lecture of the Physical Society of London, The, Dr. C. E. Guillaume, 438
Gymnospermic History, 97
Gypsum, The Fibrous, of Nottinghamshire, W. A. Richardson, 569
Gyrostat, a Non-spinning, Rotation of, and its Effect in the Aeroplane Compass, G. T. Bennett, 378
Gyrostatic Compass, The, S. G. Brown, 44, 77

Hæmoclasic Crisis, The Possibility of Promoting the, by the Intravenous Injection of Portal Blood Collected During the Digestive Period, F. Widal, P. Abrami, and M. N. Iancovesco, 699
Hailstorm, The Survey, of July 16, 1918, J. E. Clark, 281
Half-past Twelve: Dinner-hour Studies for the Odd Half-hours, G. W. Gough, 611
Halo, A Peculiar, Capt. C. J. P. Cave, 171
Hardwoods of Australia, The, and Their Economics, R. T. Baker, 802
Hardy Fruit Culture: Practical, R. Staward, 545; The Elements of, 545
Harmonics in the Neighbourhood of an Assigned Function, T. Levi-Civita, 844
Hastings Coast-line, The Evolution of the, Miss E. M. Ward, 82
Hawaian Islands, Rainfall in the, 181; People, The Religion and Origin of the, Kamagau; S. N. Haleole; Judge Fornander; S. H. Ray, 628
Hawaii, Derivation of the Flora of, Prof. D. H. Campbell, 217
Hawthorn Blossom, Early, Lady Jenny Rose, 234
Hayden Memorial Medal of the Academy of Natural Sciences of Philadelphia, The, Awarded to Prof. T. C. Chamberlin, 399
Hazel-nut, The Supposed Parthenocarpy of the, and its Possible Characters, II., A. Trotter, 251
Health and the Teacher, 259
Heat: Economy, Prof. A. Witz, 212; The Theory of, Prof. T. Preston, Third Edition, Edited by J. R. Cotter, 228
Hejaz, Discoveries in the, Dr. D. G. Hogarth, 528
Helium: in the British Empire, Sources of, Prof. J. C. McLennan, 725; Its Discovery and Applications, Dr. W. J. S. Lockyer, 360; Its Production and Uses, Prof. J. C. McLennan, 747, 778
Hereditas, No. I., 558
Hereford Cattle, Colour and Markings of Pedigree, Miss F. Pitt, 211
Heron of Castle Creek, The, and Other Sketches of Bird Life, A. W. Rees, 514
Heterophyidæ, A Synopsis of the Trematode Family, Dr. B. H. Ransom, 786
Hettangian Iron Minerals of Burgundy, The, L. Cayeux, 443
Hevea brasiliensis, Structure and Development of the Woody "Burrs" or "Nodules" in, G. Bryce, 20
Hidden Treasure: The Story of a Chore Boy who made the Old Farm Pay, J. T. Simpson, 36
High Levels in the Atmosphere: The Attainment of, Prof. A. McAdie; Dr. J. G. Coffin, 437; W. H. Dines, 454
High-voltage Corona in Air, Prof. J. B. Whitehead, 842
Hill Observatory, Sidmouth, Report of the, 726
Hindu Drama: The Origin of the, Additional Evidence, Sir W. Ridgeway and Dr. L. D. Barnett, 433
Hinduism, The Enduring Power of, Sir Valentine Chirol, 834
Hittite Civilisation, The, Prof. M. Jastrow, jun., 763
Holopus, a Dried Specimen of, Found in Barbados, Dr. C. T. Trechmann, 757
Holothurioidea of the Coasts of Ireland, Species of, Miss Anne L. Massy, 433
Honey-bees, Cause of Death of, Mrs. Pixell-Goodrich, 53
Hong-Kong, Meteorology at, 244; Royal Observatory, Report for 1919 of, 788
Hood, H.M.S., 182
Hooker Telescope, The 100-in., Some Tests of, Dr. G. E. Hale, 266
Hot Filaments, The Thermionic Properties of, Experiments on, Dr. F. L. Hopwood, 473
House of the Morning," "The, in Egyptian Ritual, Dr. A. M. Blackman, 241
Huddersfield Technical College, Gift to, by Mrs. M. Blamires, 185
Human Body, The Engines of the, Prof. A. Keith, 195
Hurter and Driffield: A Memorial Volume Containing an Account of the Photographic Researches of Ferdinand Hurter and Vero C. Driffield: Being a Reprint of their Published Papers, together with a History of their Early Work and a Bibliography of Later Work on the Same Subject, Edited by W. B. Ferguson, 609; Memorial Lecture, The, Prof. A. Findlay, 689; F. F. Renwick, 689
Hydrazine, Action of, on the 1:4 Acyclic Diketones, E. E. Blaise, 506
Hydrazines, The Action of Substituted, upon Acyclic 1:4 Diketones, E. E. Blaise, 666
Hydrocyanic Acid, The Action of, on Glucose, J. Bougault and J. Perrier, 539; on the Organism of Plants, J. Stoklasa, 539
Hydro-electric Power Works at the Great Lake, Tasmania, The, 690
Hydrogen: Molecule, The Structure of the, Diamagnetism and, Dr. A. E. Oxley, 581; Peroxide, The Acceleration of the Decomposition of, by Colloidal Rhodium, C. Zenghelis and B. Papaconstantinos, 443; The Diamagnetism of, Dr. J. R. Ashworth, 645; The Secondary Spectrum of, Prof. J. W. Nicholson, 166
Hydrographical Studies, Prof. D'Arcy W. Thompson, 150; Surveying, the late Rear-Admiral Sir W. J. L. Wharton, Fourth Edition, Revised and Enlarged by Admiral Sir Mostyn Field, 576
Hydrolysing Action of Emulsin, Presence in the Melilot and Woodruff of Glucosides Furnishing Coumarin under the, Em. Bourquelot and H. Hérissey, 634
Hygiene, Army, and its Lessons, Lieut.-General Sir Thomas Goodwin, 532; for Training Colleges, A Text-book of, Margaret Avery, 259
Hymenoptera, The Parasitic Aculeate, Prof. W. M. Wheeler, 835
Hyperbolic Space, Relativity and, Prof. A. McAulay, 808
Hyperion, The Theory of, Investigations in, Dr. J. Woltjer, jun.; Dr. A. C. D. Crommelin, 675
Hysteresis Values when Using High Magnetising Forces, The Measurement of, W. L. Cheney, 838

Ibérica, A New Spanish Scientific Journal, 755
Ice, Curious Formation of, A. S. E. Ackermann, 741; in Arctic Seas, State of the, 275
Ignition Points of Liquid Fuels, H. Moore, 245
Illuminating Engineering Society, Report of the Council of the, 402
Imitation of Cells, Tissues, Cell-Division, and the Structure of Protoplasm with Calcium Fluosilicate, A. L. Herrera, 635
Imperial: Air Routes, Major-General Sir Frederic H. Sykes, 359; College of Science and Technology, Provision of Post-Graduate Scholarships at American Universities, 89, 173; Claim of the, to University Status, Lord Morris, and others, 471; The Department of Aeronautics, The Work and Staff of the, 841; Entomological Conference, The Forthcoming, 398, 432, 502; War Museum, The Formation of the, Sir Martin Conway, 626; Wireless Telegraph Committee, Report of the, 594
India: A Chemical Service for, Prof. H. E. Armstrong, 669; Map-making in, 277; Scientific Work in, The Organisation of, Sir Thomas H. Holland, 452, 565; Sugar Cultivation in, Dr. W. E. Brenchley, 840; Survey of, Report for 1915-16 of the Records of the, 277; The Census of 1921, Consideration of the Prin-

ciples of, 338; The Linguistic Survey of, Sir George Grierson, 688
Indian: Beetles, 64; Bauxites, Dr. L. L. Fermor, 212; Chemical Service, The, Prof. Jocelyn Thorpe, 324; Sir Prafulla Chandra Rây, 325; Dr. M. W. Travers, 354; Students in America and Japan, Facilities for, R. K. Sorabji, 377
Indians North of Mexico, Calendars of the, Miss L. Cope, 75
Indo-Aryan Vernaculars, The, Sir George Grierson, 557
Induction Coil, Action of the, Prof. E. T. Jones, 369
Indus, Brahmaputra, and Ganges, Relations of the, Dr. E. H. Pascoe, 835
Industrial: Efficiency and Factory Management, Bibliography of, H. G. T. Cannons, 641; Fatigue Research Board, First Annual Report of the, 786; Seventh Report of the, S. Wyatt, 657; Fellowship System for the Promotion of Industrial Research, The, T. Ll. Humberstone, 665; Peace, The Road to, 55; Psychology, The Present Attitude of Employees to, Mrs. S. Brierley, 400; Research, A. P. M. Fleming, 771; Applied Science and, J. W. Williamson, 387; Prof. F. Soddy, 422; Major A. G. Church, 423; J. W. Williamson, 518; Scientific Direction of, Major A. G. Church, 40; Scientific Research, The Organisation of, Dr. C. E. Kenneth Mees, 771
Industry, Optical Instruments in, 394
Influenza: Dr. Carnwath, 151; Epidemic of 1918-19 in Switzerland, The, 400; on Shipboard, Majors McKendrick and Morison, 400; Returns, 274, 367; of the Registrar-General, 557; The Relation of the *Bacillus influenzæ* to, Dr. F. G. Blake, 763
Infra-red Arc Spectra of Seven Elements, The, C. C. Kiess and W. F. Meggers, 726; Spectra of Nebulæ, W. H. Wright, 149
Injurious Insects Observed in Ireland During 1916-18, Prof. G. H. Carpenter, 634
Insect: Life on Sewage Filters, Dr. W. H. Parkinson and H. D. Bell, 131; Life: Wonders of, Details of the Habits and Structure of Insects, J. H. Crabtree, 651; Pests, Artificial versus Natural Methods of Control of, F. W. Urich, and others, 503; Control of, L. Lloyd; E. B. Blakeslee; F. S. Brooks; C. F. C. Beeson, 629; W. J. Phillips, 662; F. C. Bishop and H. P. Wood, 663
Insects of Arctic Canada, 730
Institute: of Industrial Administration, Foundation of the, E. T. Elbourne Elected Honorary Secretary, 754; of Metals, The May Lecture of the, 499; of Optics of France, Work at the, A. de Gramont de Guiche, 466
Institution of Sanitary Engineers, The Gold Medal of the, Presented to Major A. J. Martin, 526
Integration, Approximate, Some Methods of, and of Computing Areas, A. S. Percival, 70
Intellectual Stock-taking, 607
Interference Methods, The Application of, to Astronomical Measurements, A. A. Michelson, 666
Interferometer, The, in Physical Measurements, 563
Interferometry, Displacement, by the Aid of the Achromatic Fringes, Prof. C. Barus, 563
International: Bureau of Weights and Measures at Sèvres, The, 242; Council for Fishery Investigations, Prof. W. C. McIntosh, 167, 358; Federation of University Women, First Conference of the, 662; Fishery Investigations, 84; Research Council: Constitutive Assembly held at Brussels, July 18th to July 28th, 1919, Report of Proceedings, Edited by Sir Arthur Schuster, 543
Intrusive Rocks of the Dundee District, The, D. Balsillie, 666
Inulin, The Diastatic Hydrolysis of, H. Colin, 380
Inventor, Relations of the, to the State, D. Leechman, 366; W. F. Reid, 367
Invertin in Pure Honey, The Search for, A. Caillas, 218
Iodic Acid: as a Microchemical Reagent Characteristic of Gaseous Ammonia, G. Denigès, 763; as a Microchemical Reagent for Calcium, Strontium, and Barium, G. Denigès, 379
Iodine, Sorption of, by Carbon, J. B. Firth, 602
Iodoamidines, The, J. Bougault and P. Robin, 666
Ionisation: and Activity of largely Ionised Substances, A. A. Noyes and D. A. MacInnes, 667; in the Solar Chromosphere, M. N. Saha, 232
Ions, Electrons, and Ionising Radiations, Dr. J. A. Crowther, 740
Ireland: Department of Agriculture and Technical Instruction, Impending Retirement of T. P. Gill from the Secretaryship of the, 376; The Peat Resources of, Prof. P. F. Purcell, 791
Irish Eskers, The, Prof. J. W. Gregory, 346
Iron: and Steel Industry in Lorraine, The Future of the, Prof. H. C. H. Carpenter, 588; and Steel Institute, Annual Meeting of the, 179; Presidential Address to the, Dr. J. E. Stead, 403; Trades during the War, The, M. S. Birkett, 787; Bacteria, Dr. D. Ellis, 323; Cast, The Heat Treatment of, 290; Core of a Transformer or of an Induction Coil, Magnetic Characteristics of the, The Late Prof. B. O. Peirce, 243; -depositing Bacteria, Dr. D. Ellis, 727; and their Geologic Relations, E. C. Harder, 727; Ores of Scotland, The, M. Macgregor, and others, vol. XI., 419; The Deposition of, by Electrolysis, W. E. Hughes, 594
Ishi, The Medical History of, S. T. Pope, 755
Isis, and other Periodicals dealing with the History of Science, 241
Isomerism, An Electric Theory of, Dr. H. S. Allen, 71; W. E. Garner; S. C. Bradford, 171
Isotopes: and Atomic Weights, Dr. F. W. Aston, 617; The Separation of, Dr. T. R. Merton and Brig.-Gen. H. Hartley, 104; of Chlorine, The Separation of the, D. L. Chapman, 487, 611; Prof. F. Soddy, 516, 642; A. F. Core, 582, 677
Italy, Agriculture in, in Imperial Times, W. E. Heitland, 557

Jamaica, Flora of, Vol. IV., Dicotyledons: Families Leguminosæ to Callitrichaceæ, W. Fawcett and Dr. A. B. Rendle, 738
Japan, Effect of Topography on Precipitation in, Prof. Terada, 599
Japanese Botanical Work, 664
Java, Long-range Forecasting in, 729
Jib, a Long Wooden, for a Derrick Crane, 838
Jupiter: Conjunction of, with Neptune, 213; The Great Red Spot on, W. F. Denning, 423; The Planet, Rev. T. E. R. Phillips, 500
Just Look! or, How the Children Studied Nature, L. Beatrice Thompson, 651

K and L Absorption of the Heavy Elements, Calculation of the Limiting Frequencies of, L. de Broglie, 218
Kalahari, The, and Ovamboland, Prof. E. H. L. Schwarz, 297
Karroo System, The Reptilian Fauna of the, S. H. Haughton, 837
Karthala Volcano, An Eruption of the, at Grand Comore in August, 1918, A. Lacroix, 666
Katharometer, The Theory of the, H. A. Daynes, 122
Kent's Cavern, The Condition of, E. A. Martin, 742
Kerr Phenomenon, The Ratio of the Absolute Retardations in the, for Different Wave-lengths in the case of Nitrobenzene, M. Pauthenier, 634
Ketimines, The, G. Mignonac, 347
Kew, Royal Botanic Gardens: Bulletin of Miscellaneous Information, 1919, 228; Official Guide to the Museum of British Forestry at the, 211; Question of Guide Lectures at the, Lord Sudeley, 178
King's Birthday Honours, The, 462
King's College, London: decision to form an Old Students' Association in connection with, 217; Post-Graduate Courses for Engineers, 313
Kingsley, Mary, Medals, Award of, 696
Kitchener, Lord: as a Scientific Worker, 319; Life of, Sir George Arthur, 3 Vols., 319
Knowledge: and Power, 93; L. Bairstow, 135; F.O.I.: Dr. J. W. Evans, 165; and Understanding, 1
Kodaikanal Observations of Prominences, J. and Mrs. Evershed, 340

Koheleth, Book of, commonly known as Ecclesiastes, A Gentle Cynic: Being a Translation of the, stripped of Later Additions; also its Origin, Growth, and Interpretation, Prof. M. Jastrow, Jun., 226
Krueger 60, The Binary, S. A. Mitchell and C. P. Olivier, 307
Krypton and Xenon, Notes on, Prof. J. N. Collie, 441
Kula: The Circulating Exchange of Valuables in the Archipelagoes of Eastern New Guinea, Dr. B. Malinowsky, 688
Kynurenic Acid in the Dog, Mechanism of the Production of, Prof. A. Robinson, 346

Laboratory Fittings: Scientific Apparatus and, C. Beck, 355; B. H. Morphy; C. Baker, 356; Bellingham and Stanley, Ltd.; W. Taylor; H. W. Ashfield, 357; The Cost of, A. E. Munby, 294, 456
Lad: A Dog, A. P. Terhune, 484
Laird, Cammell, and Co., Ltd., The Birkenhead Shipyard and Works of, 560
Lake: District, The Vulcanicity of the, J. F. N. Green, 242; Geneva, The Theoretical Determination of the Longitudinal Seiches of, Doodson, Carey, and Baldwin, 275
Laminarine from *Laminaria flexicaulis*, The Study of, Mme. Z. Gruzewska, 187
Lancashire Sea-Fisheries Laboratory, Report of the, for 1919, 656
Land: and Water in the North Atlantic Region in Palæozoic Times, The Distribution of, Dr. Holtehahl, 212; Land and Water on the Earth, Distribution of, Prof. H. F. Reid, 763; Drainage from the Administrative Point of View, E. M. Konstam, 42; Land Flora, The Earliest Known, Prof. F. O. Bower, 681, 712; from the Engineering Point of View, C. H. J. Clayton, 42; Rainfall and, Dr. Brysson Cunningham, 42; Mollusks of the Belgian Congo, Dr. H. A. Pilsbry, 433
Langmuir's Theory of Atoms, On: S. C. Bradford, 41; Dr. A. E. Oxley, 105
Larch, The Common, The Fungal Diseases of, W. E. Hiley, 639
Latitude, An Easy Method of Finding, N. Liapin, 625
League of Nations Union, Forthcoming Summer School in connection with the, 280
Leather Chemistry, Practical, A. Harvey, 382
Leeds University: W. E. H. Berwick appointed Lecturer in Mathematics in, 56; Dr. H. M. Dawson appointed Professor of Physical Chemistry, 409; Increase in the Scale of Fees, 697; Institution of an Appointment Board, with W. R. Grist as Secretary; G. C. Stewart appointed Assistant Lecturer in Applied Mathematics, 698
Leonardo da Vinci, E. McCurdy, 307, 340
Lepidoptera, British, Melanism in, J. W. H. Harrison; Hon. H. Onslow, 278
"Les Maîtres de la Pensée Scientifique," 788
"Les Océans à travers les âges," Prof. P. Termier, 624
Lethargic Encephalitis, 785
Lettuce, The Meiotic Phenomena in the Pollen Mother-Cells and Tapetum of, Dr. R. R. Gates, 186, 756
Levelling Errors, 400
Libraries in Indian High Schools, L. T. Watkins, 698
Life: and Existence, Wisdom of, 226; and Temperature, 161; Movements in Plants, Sir Jagadis Chunder Bose, 416; The Processes of, The Dualistic Conception of, Dr. S. J. Meltzer, 763
Light: and Plant-Growth, The Relationship between, W. W. Garner and H. A. Allard, 464; Production in Luminous Organisms, The Chemistry of, E. N. Harvey, 270; Scattered by Gases in respect of Polarisation, A Re-examination of the, I., Lord Rayleigh, 631; The Absorption of, by Organic Compounds, 640; Deflection of, during a Solar Eclipse, J. A. Orange; Dr. A. C. D. Crommelin, 8; Marat and Prof. W. A. Osborne, 456; Destructive Effect of, on Textiles, etc., M. Entat, 758; Filters for Visual Work with the Microscope, Kodak Ltd., 435; The Einstein Deflection of, Dr. A. C. D. Crommelin; Prof. C. V. Raman, 23
Lighting: Conditions in Mines, with special reference to the Eyesight of Miners, Dr. T. L. Llewellyn, and others, 21; of Picture-Galleries and Museums, The, H. Seager, 723
Lightning Discharges, Investigations on, and on the Electric Field of Thunderstorms, C. T. R. Wilson, 377
Lime and Magnesia carried down by Precipitates of Ferric Oxide, The, M. Toporescu, 475
Linné, Carl von, Movement to Restore the Botanic Garden and House of, 591
Linnean Society: Election of Officers and Council of the, 496; Profs. G. Bonnier, V. F. Brotherus, G. B. de Toni, L. Dollo, P. Marchal, and R. Thaxter elected Foreign Members of the, 366; The Financial Position and Outlook of the, 80; The Gold Medal of the, Presented to Sir Ray Lankester, 526
Linnean Society of N.S.W., Presidential Address to the, J. J. Fletcher, 724
Liquid: Cylinders, Rotating, C. R. U. Savoor, 379; Fuels, Ignition Points of, H. Moore, 245; Mercury, The Thermo-Electricity of, Verification of, M. Gouineau, 634
Liquids at High Pressure, Viscosities and Compressibilities of, J. H. Hyde, 57
Lister: Lord, Proposals for Commemorating the Work of, 654; Institute of Preventive Medicine, Establishment at the, of a National Collection of Type Cultures, 590
Liverpool: School of Tropical Medicine, Inception and History of the, 785; Opening of the Sir Alfred Jones Laboratories of the; Award of Mary Kingsley Medals, 696; University, Appeal for Funds, 121; Contribution by the King to the Appeal Fund, 601; Gift to the Appeal Fund by the Pacific Steam Navigation Co., 762; Gift to, by the Cunard Steamship Co., 313, 762; Gift by T. Harrison Hughes, 345; Dr. C. Walker appointed Associate-Professor in Cytology and Lecturer in Histology; J. Wemyss Anderson appointed Professor of Engineering Refrigeration, Gifts to the Appeal Fund, 376; Conferment of Honorary Degrees, 440; Resolution of the Senate on the Death of Prof. L. Doncaster, 472; T. R. Wilton appointed Lecturer in Dock and Harbour Engineering, 505; Dr. W. J. Dakin appointed Professor of Zoology; Dr. I. M. Heilbron Professor of Organic Chemistry, 537; Dr. W. Mason appointed Professor of Engineering (Strength of Materials); C. O. Bannister Professor of Metallurgy, and W. H. Gilmour Professor of Dental Surgery, 630; The Title of Emeritus Professor of Engineering conferred upon Prof. H. S. Hele Shaw, 841
Local Colleges and Adult Education, Principal L. Small, 728
Local Government Board, The Origin and Growth of the Medical Department of the, Sir George Newman, 151; Forty-eighth Annual Report of the, 151
Long-range Forecasting in Java, 729
London: County Council, Compulsory Day Continuation Schools, Forthcoming Appointment of Principals of, 280; Draft Scheme, The, The Education Act, 1918, 693; Degrees in Commerce, Dr. Russell Wells, 440; School of Economics, The Foundation-Stone of the New Wing of the, Laid by the King, 440; University, Appointment of Fellows of University College; The Degree of D.Sc. conferred on W. Rees, 25; Gifts to, by the Sir Ernest Cassel Educational Trust; Dr. J. McIntosh appointed Professor of Pathology at the Middlesex Hospital Medical School; Dr. S. Russ appointed Professor of Physics at the Middlesex Hospital Medical School, 25; Appeal for a War Memorial, 57; W. Neilson-Jones appointed Professor of Botany at Bedford College; Posts in connection with the Sir Ernest Cassel Benefactions; Various Gifts; Conferment of Doctorates; Award of Keddey Fletcher-Warr Studentships to Dr. Agnes Arber and Miss Margaret McFarlane; Annual Report of University College, 155; Forthcoming Public Lectures, 313; Courses of Advanced Lectures, 376; The University of, A Great Opportunity, 381; Government Offer of a Site, H. A. L. Fisher, 404; The Degree of D.Sc. conferred on B. C. Laws; Report

of the Principal Officer for 1919-20, 409; Site and Needs, Sir E. Sharpey Schafer, 484; and the British Museum, Chance of Increased Co-operation between, 528; Dr. S. Russell Wells re-elected Vice-Chancellor; Acceptance of the Rockefeller Gift; Appointments; Grants from the Dixon Fund, 568; The Degree of Bachelor of Science in Household and Social Science to be Instituted, 569; Resolution *re* the Proposed Site for, 569; E. Barker appointed Principal of King's College, 630; Mr. Fisher on King's College, 665; V. H. Mottram appointed Professor of Physiology at King's College for Women Household and Social Science Department; Dr. W. S. Lazarus-Barlow appointed Professor of Experimental Pathology at Middlesex Hospital Medical School; Dr. J. C. Drummond appointed University Reader in Physiological Chemistry at University College, 698; Conferment of Doctorates; The Proposed Site; Appointments at King's College, 698; University College, Opening of the New Buildings of the Department of Applied Statistics, 470
Longitude by Wireless Telegraphy, Prof. R. A. Sampson, 370
Lorraine, The Future of the Iron and Steel Industry in, Prof. H. C. H. Carpenter, 588
Louth: Disastrous Flood at, 432; The Thunderstorms of May 29, and the, 468; The Flood at, 504
Lower Carboniferous Chert-formations of Derbyshire, The, H. C. Sargent, 58
Lower Palæozoic Rocks of the Arthog-Dolgelley District, The, Prof. A. H. Cox and A. K. Wells, 123
Lubricants, Solid, Memorandum on, T. C. Thomsen, 372
Lubricating Oils, Methods of Examining, Plea for Uniformity in, G. F. Robertshaw, 339
Lubrication, The Theory and Practice of, Wells and Southcombe, 21
Luciani, Prof. L., Life and Work of the late, Sig. Baglioni, 844
Luck, or Cunning, as the Main Means of Organic Modification? An Attempt to Throw Additional Light upon Darwin's Theory of Natural Selection, S. Butler, second edition, 773
Lunar: Eclipse, The, 307; Parallax, The, and Related Constants, Prof. W. de Sitter, 529; Tides, The Effects of, on the Earth's Atmosphere, Prof. S. Chapman, 506

McGill University: Resignation of the Principalship of, Sir Auckland C. Geddes, 17; Dr. L. V. King appointed Macdonald Professor of Physics at the Macdonald Physics Building of, 721
Macgregor, The Dr. Jessie, Prize for Medical Science, Forthcoming Award of, 377
Machine Drawing, A Text-book on, for Electrical Engineers, E. Blythe, 260
Mackinder's "World Island" and its American "Satellite," C. R. Dryer, 624
Madras, Flora of the Presidency of, J. S. Gamble, part iii., 36
Madrid Observatory, Annual of the, for 1920, 213
Magnet Steel, Bars of, The Testing of, Dr. N. W. MacLachlan, 122
Magnetic: Declination, Simultaneous Values of, at Different British Stations, Dr. C. Chree, 632; Disturbances and Geological Structure, 175; Disturbances in Northamptonshire and Leicestershire, A Report on, and their Relations to the Geological Structure, Dr. A. H. Cox, 175; Induction in the Soft Iron Compass Correctors under the Influence of the Needles, L. Dunoyer, 539; Shell Equivalent to a Given Electric Current, The Construction of a, Dr. A. A. Robb, 100; Storm of March 4-5, Dr. C. Chree, 56; of March 22-23, The, and Associated Phenomena, Dr. C. Chree, 136; Rev. A. L. Corbie, 137; and Associated Phenomena, Dr. A. Crichton Mitchell, 170
Magnetism: and Electricity, Intermediate Text-book of, R. W. Hutchinson, 515; Notes on, for the Use of Students of Electrical Engineering, C. G. Lamb, 193; The Decay of, in Bar Magnets, Prof. W. Brown, 123
Magnets, Permanent, in Theory and Practice, S. Evershed, 435
Malaya, Food Production in, F. G. Spring and J. N. Milsum, 180
Malleable Cast Iron, S. J. Parsons. Second edition, 290
Mammalia, Tongues of the, Comparative Anatomy of the, Dr. C. F. Sonntag, 218
Mammalian Remains from Cuba and Porto Rico, H. E. Anthony, 757
Man: Past and Present, Prof. A. H. Keane. Revised, and largely re-written, by Mrs. A. H. Quiggin and Dr. A. C. Haddon; Prof. G. Elliot Smith, 255; The Ascent of, 708; The Asiatic Origin of, W. B. Wright, 728
Manchester: College of Technology, Work of the, in the War, 410; Resignation of J. C. M. Garnett of the Principalship of the, 630; Literary and Philosophical Society, Sir Henry A. Miers re-elected President of the, 303; J. H. Lester elected Chairman of the Chemical Section of the, 335; University, Grant from the Carnegie United Kingdom Trust for the Foundation and Maintenance of a Library for Deaf Education, 155; Developments at, 278; The Appeal Fund of, 313; Gift by the King to the Appeal Fund, 630; J. Higham appointed Lecturer in Physics and Electrical Engineering, 698
Manganese Ores, A. H. Curtis, 193
Manures: Soils and, A Student's Book on, Dr. E. J. Russell, Second edition, 130; and, in New Zealand, L. J. Wild, 130
Maori Daggers, Two Wooden, Sir W. Ridgeway, 274
Map-making in India, 277
Maps, New Ordnance Survey, Lt.-Col. W. J. Johnston, 312
Marat and the Deflection of Light, Prof. W. A. Osborne, 456
Marine: Algæ as Food for the Horse, Lapicque and Brocq-Rousseu, 635; Biological Association, Annual General Meeting of the, Sir E. Ray Lankester re-elected President, 303; Biological Structures and Functions, 279; Deposits, The Transfer of, from the Sea-floor to the Surface of Glacier Ice, F. Debenham, 724; Diesel Engine, The Running and Maintenance of the, J. Lamb, 290
Mariner's Compass, The, 44
Marlborough College Natural History Society, Report for 1919, 337
Marriages between Hindus of Different Castes, Bill to Make Valid, 241
Mars: and Wireless Signals, 276; Conjunction of, with Spica, 340; Different Phenomena Observed on the Planet, R. Jarry-Desloges, 603
Martres d'Artières (Puy-de-Dome), The Geyser of, Ph. Glangeaud, 315
Mason-Wasps, The, J. H. Fabre. Translated by A. T. de Mattos, 291
Maternity and Child Welfare, Dr. Wheaton, 151
Mathematical: Books and Pamphlets, Gift of, to the South African Public Library, Cape Town, by Sir Thomas Muir, 305; Cosmogony, 31; Text-books, Recent, 162
Mathematician as Anatomist, The, Prof. A. Keith, 767
Mathematics: Critical, 256; for Collegiate Students of Agriculture and General Science, Prof. A. M. Kenyon and Prof. W. V. Lovitt. Revised edition, R. A. Fisher, 31; for Engineers, part ii., W. N. Rose, 260; of Elasticity, 511; Pure and Applied, Dr. S. Brodetsky, 65; Unified, Profs. L. C. Karpinski, H. Y. Benedict, and J. W. Calhoun, 162
Mathématique, Les Principes de l'Analyse, Exposé Historique et Critique, Prof. P. Boutroux. Tome second, 256
Matrices and Determinoids, Prof. C. E. Cullis, vol. ii., 191
Matter, Some Wonders of, Rt. Rev. Dr. J. E. Mercer, 67
Maulund Klauenseuche, Neue Beobachtungen über den Erreger der: Die Entwicklung des Schmarotzers im Blut, speziell in den roten Blutkörperchen, Dr. H. Stauffacher, 100
Mean Values, Equivalence of Different, A. Kienast, 474

Meat and Milk in the Food Supply of the Nation, Report on, 400
Mechanical: Engineers, Institution of, Researches under the Direction of the, 53; Reduction Gears, Use of, between the Turbines and the Propeller in the Royal Navy, Eng.-Comdr. H. B. Tostevin, 148
Mechanics, School, part i., School Statics, W. G. Borchardt, 163
Medical: Discovery, Awards for, Visit of a Deputation of the British Medical Association and the British Science Guild on, to Mr. Balfour, 18; Education, 573; Science in, Prof. S. J. Hickson, 643; Research, Prof. G. Elliot Smith, 605; and the Practitioner, 541; Committee, The Work of the, 43; The Work of the, Sir Walter Fletcher, 400; The Promotion of, 221; Science and Education, Sir T. Clifford Allbutt, and others, 661; Women, Admission of Qualified, to the Fellowship of the Royal College of Surgeons of Edinburgh, 51
Medicine, Medieval, Prof. J. J. Walsh, 127; Poetry and, Prof. D'Arcy W. Thompson, 414
Mediterranean Oceanography, A Project for Systematic Exploration in, 113
Melanism in British Lepidoptera, J. W. H. Harrison, Hon. H. Onslow, 278
Meliola and Irene, The haustoria of the Genera, Miss Ethel M. Doidge, 667
Melissic Alcohol of Brodie, The, A. Gascard, 314
Memories, Lord Fisher, 95
Memory: and Conation, Miss Edgell, 603; Unconscious, S. Butler. Third edition, 774
Mensuration for Marine and Mechanical Engineers (Second- and First-class Board of Trade Examinations), J. W. Angles, 163
Mercuric Salts, Precipitation of, by Sulphuretted Hydrogen, P. Jolibois and P. Bouvier, 603
Mercury: Arc, A New Alternating, H. Georges, 91; as an Evening Star, 529; Conjunction of, with ε Geminorum, A. Burnet, 370; the Motion of, A Dynamical Specification of, G. W. Walker, 198; Vapour, Low-voltage Ionisation Phenomena in, K. H. Kingdon, 632
Metabolism of Boys from One to Thirteen Years of Age, The Basal, F. G. Benedict, 667
Metal-foil Surfaces in Rarefied Gases, The Forces Acting on Heated, G. D. West, 122
Metals: Heat Conductivities of, S. Konno, 181; Institute of, The Autumn Meeting of the, to be Held at Barrow-in-Furness, 366; The Journal of the, vol. xxii., No. 2, 1919. Edited by G. Shaw Scott, 164; Minerals and, 193; Spectrographic Detection of, especially Zinc, in Animal Organisms, A. de Gramont, 411; The Elastic Properties and the Plastic Extension of, Prof. W. E. Dalby, 377; The Mineralogy of the Rarer, A Handbook for Prospectors, E. Cahen and W. O. Wootton. Second edition, revised by E. Cahen, 259
Meteor Shower, The April, 276
Meteoric Iron of Mount Ayliff, Griqualand East, The, Dr. G. T. Prior, 156
Meteorite, An Interesting, G. P. Merrill, 759
Meteorological: Conditions of an Ice-cap, R. F. T. Granger, 709; Conference, International, Work of the Paris Meeting of the, 180; Influences of the Sun and the Atlantic, Prof. J. W. Gregory, 715; Instruments, C. F. Casella and Co.'s Catalogue of, 20; *Magazine, The*, 83; Observations in Netherlands East India, 1917, 758; at St. Xavier's College, Calcutta, Rev. E. Francotte, 55; Office, The Position of the, W. W. Bryant, 38; Dr. H. R. Mill, 38; Resolution of the Scottish Meteorological Society on, 87; Impending Retirement of Sir Napier Shaw from the Directorship of the, 144; Dr. G. C. Simpson appointed Director of the, 721; Variations, Short-period, Dr. E. van Rijckevorsel, 761
Météorologie, Manuel Pratique de, J. Rouch, 451
Meteorology, Aerial Navigation and, Prof. E. van Everdingen, 637, 776; Lt.-Col. E. Gold, 775; at Hong-Kong, 244; for All: Being some Weather Problems Explained, D. W. Horner, 323; in Gunnery, The Importance of, Dr. E. M. Wedderburn, 492; of the Temperate Zone, The, and the General Atmospheric Circulation, Prof. V. Bjerknes, 522; Weather Forecasts and, A. Mallock, 580
Meteors: April, 149; Bright, 54; Great Perseid Shower of, Commencement of the, 595
Methods, Dr. J. McK. Cattell, 795
Methwold, Norfolk, The National Demonstration Farm at, 179
Methyl: Chloride and Bromide, The Preparation of, starting from Dimethyl Sulphate, Ch. Boulin and L. J. Simon, 218; Esters, Combustion of, with a Mixture of Sulphuric and Chromic Acids, J. Guyot and L. J. Simon, 187
Methylethyl*cyclo*hexanone, The Constitution of the, prepared by the Ethylation of α-Methyl*cyclo*hexanone, A. Haller and R. Cornubert, 379
Metric Literature Clues, 179
Mica Industry, The, in Eastern Transvaal, A. L. Hall, 787
Mice, Spotting in, Sô and Imai, 400
Micro-organisms, The Projection of, into the Air, A. Trillat and M. Mallein, 475
Microscopic Illumination, Dr. H. Hartridge, 275
Microscopy, Quantitative, The Lycopodium Method of, T. E. Wallis, 249
Microtome, A Universal, Sir Horace Darwin and W. G Collins, 570
Middle Cambrian Beds at Manuels, Newfoundland, The, and their Relations, B. F. Howell, jun., 843
Middlesex Hospital, Reorganisation and Co-operation of Research Departments of the, 240
Migrations in the Sea, The Physiology of, Prof. A. Meek, 196
Military Hygiene, Gen. Sir John Goodwin, 114
Milk: and Apthous Fever, C. Porcher, 699; and Hæmolysis, H. Violle, 411; Problem, The Modern, in Sanitation, Economics, and Agriculture, J. S. MacNutt, 385; Production of Ayrshire Cattle, Prof. R. Pearl and J. R. Miner, 245; The Problem of Clean and Safe, Prof. S. Delépine, 385; The Story of, J. D. Frederiksen, 229
Mind Training, Technical Education and, E. L. Rhead, 439
Mineralogical Abstracts, part i., 147
Mineralogy of the Rarer Metals, The, A Handbook for Prospectors, E. Cahen and W. O. Wootton. Second edition, revised by E. Cahen, 259
Minerals: and Metals, 193; from Monte Somma and Vesuvius, Prof. G. Cesàro, 464
Mines in the Pas-de-Calais District, and the Method of Working Them, G. S. Rice, 688
Models Illustrating the Atomic Arrangement in Potassium Chloride, etc., W. Barlow, 570
Mole Cricket, The, F. V. D., 294
Molecular Energy in Gases, The, Sir Alfred Ewing, 472
Mollusca Obtained by the Crocker Land Expedition, Dr. W. H. Dall, 688
Monarch: The Big Bear of Tallac, E. Thompson Seton, 450
Monkey, The Antiscorbutic Requirements of the, Drs. A. Harden and S. S. Zilva, 499
Monoclinic Double Selenates of the Copper Group, Dr. A. E. H. Tutton, 538
Monsoon Rainfall in 1920. The Probable Amount of, Dr. G. T. Walker, 1920, 724
Montefiore, Fondation George, Prize, 834
Montgomery, Mary Louisa Prentice, Lectureship in Ophthalmology, Prof. G. Elliot Smith elected to the, 240
Moon: Eclipse of the, 276; Photograph of the, F. G. Pease, 267
Morocco, Some Results of a New Journey in, A. Brives, 475
Mortlakes as a Cause of River-windings, T. S. Ellis, 264; H. Bury, 391
Moseley Memorial, Sir Henry A. Miers, C. G. Darwin, Dr. H. Robinson, 200
Motion: High-speed, Langrangian Methods for, C. G. Darwin, 379; Study and the Manual Worker, 737; for the Handicapped, F. B. and Dr. L. M. Gilbreth, 737
Motor Fuels, Mixtures for Use as, Dr. W. R. Ormandy, 21
Mounting of Wet Specimens under Watch-glasses and Petri Dishes, L. Renouf, 689
Mowra Flowers, Suggested Use of, for the Manufacture of Alcohol, 147
Murchison, Charles, Scholarship in Clinical Medicine, of the Royal College of Physicians of London, The, 280

Muscle, The Thermo-elastic Properties of, A. V. Hill and W. Hartree, 537
Muscular Efficiency, A. Mallock, 197
Museums: and Art Galleries, The Lightning of, H. Seeger, 627; and the Advanced Student, Report on, 463; and the State, Prof. E. W. MacBride; Prof. J. W. Gregory, 68; Dr. F. A. Bather; Dr. W. E. Hoyle, 69; W. G. Wagner, 70; Sir E. Ray Lankester; Prof. J. Stanley Gardiner, 101; Dr. W. M. Tattersall, 102; F.R.S., 136; Association, Annual Conference, 626; National, The State and the, 29; The Proposed Transfer of, to the Local Education Authorities, Dr. F. A. Bather and Sir A. Selby-Bigge, 114
Music, The Foundations of, Dr. H. J. Watt, 98
Musical: Scale, The, J. Goold, 666; Sound, The Nature of, 98
Musings of an Idle Man, Sir R. H. Firth, 100
Musk Plants, Loss of Fragrance of, Hon. Col. C. J. Bond, 709
Mussels, Fresh-water, Correlation of Shape and Station in, Dr. A. E. Ortmann, 843
Mysticism, True and False, Dr. W. F. Geikie-Cobb, 633
Myzus ribis, Linn., Preliminary Note on Antennal Variation in, Miss Maud D. Haviland, 378

Nascent State, A New View of the, C. Zenghelis, 339
National: Education, 213; Food Consumption in the United States, Prof. R. Pearl, 597; Food Supply, The, 371; Illumination Committee of Great Britain, Major K. Edgcumbe elected Chairman of the, 557; Institute of Agricultural Botany, W. H. Parker appointed Director of the, 335; Museum of Wales, Dr. R. E. M. Wheeler appointed Keeper of the Department of Archæology, and Lecturer in Archæology in the University College of South Wales and Monmouthshire, 569; Physical Laboratory, Annual Visitation of the, 595; Report for 1919 of the, 725; Physique, A Survey of, 202; Research Council, Relation of Psychology to the, Dr. J. R. Angell, 796; Prof. V. Kellogg, 332; Union of Scientific Workers, Progress of the, 53
Native Tribes of Western Australia, The, 248
Natural: History, Misinformation and Misconception concerning, Dr. R. C. Smith, 146; Museum Pamphlets (Economic Series), New Editions of, 787; Presentation to, by Sir Henry Howorth of a Collection of Mammalian, and other Remains, 200; Staff Association, Scientific Reunion of the, 52; History, Popular, 651; Studies in Canada, 426; Knowledge, An Inquiry concerning the Principles of, Prof. A. N. Whitehead, 446; Wealth of Britain, The, Its Origin and Exploitation, S. J. Duly, 579
Naturalist, The Book of a, W. H. Hudson, 651
Nature: Hour, Stories for the, Compiled by Ada M. and Eleanor L. Skinner, 804; Pictures, Twenty-four, E. J. Detmold, 352; -study of Plants, The, in Theory and Practice for the Hobby-botanist, T. A. Dymes, 804
Nature, The Jubilee of, Congratulations upon, from the Nova Scotian Institute of Science, 113
Nautical Almanac for 1922, The, 22
Naval: Education, 445; Engineering, Progress in, Vice-Admiral Sir George Goodwin, 235; Research and Experiment, 245
Navy Estimates, A Vote for Scientific Services under the, 366
Nebulæ: Faint, E. P. Hubble, 84; Recent Researches on, H. D. Curtis, and others; Major W. J. S. Lockyer, 489
Nela Research Laboratory, The, 834
Neolithic "Floor" in the Neighbourhood of Ipswich, An Early, J. Reid Moir, 527
Neon and Helium, Moving Striations in, Dr. F. W. Aston and T. Kikuchi, 633
Neptune, Conjunction of Jupiter with, 213
Nestling Feathers of Birds, The, Prof. J. C. Ewart, 250
Netherlands, Climate of the, 600
Neuropteroid Insects of the Hot Springs Region, New Zealand, The, in relation to the Problem of Trout-food, Dr. R. J. Tillyard, 667
New Caledonia, The Botany of, R. H. Compton, 122
New Zealand: Institute, The, 24; Fellowship of the, 88; Plants and their Story, Dr. L. Cockayne. Second edition, 707; Soils and Manures in, L. J. Wild, 130; The Limestone Resources of, P. G. Morgan, 465
Newcastle-upon-Tyne, Electric Supply Co., Development of the Generating Stations of the, J. S. Watson, 369
Newtonian Fields in the Neighbourhood of a given Vectorial Field, O. Onicescu, 843
Nickel: Iron Alloys: The Anomaly of the, its Causes and its Applications, Dr. C. E. Guillaume, 438; -Steels, Expansion of the, Action of Metallurgical Additions on the Anomaly of, Ch. Ed. Guillaume, 571; Standard, Values of the Expansions of, Ch. Ed. Guillaume, 634; The Thermal Change of the Elastic Properties of, P. C. Chevenard, 603; Wire, The Change in the Rigidity of, with Magnetic Fields, Prof. W. Brown and P. O'Callaghan, 634
Night: Raid into Space, A, The Story of the Heavens told in Simple Words, Col. J. S. F. Mackenzie, 100; Sky Recorder, A, Royal Observatory, Greenwich, 281
Nile: Basin, Physiography of the, Dr. P. Chalmers Mitchell, 113; Gauges, Report upon the, for 1913-1918, H. E. Hurst, 275; Proposals for the Development of the Cultivable Area of the Valley of the, Opposition to the, 837
Nitriles: by Catalysis, A New Method of Formation of, A. Mailhe, 283; The Catalytic Hydrogenation of, G. Mignonac, 699
Nitrodichloroacetanilide, Crystalline Forms of, M. De Angelis, 844
Nitrogen: of the Cyanic Group in Manures, R. Perotti, 844; Products Committee, Final Report, 201; Problem, The: By-products, 201
Nitro-phenols, Ultra-violet Spectrophotometry of the, F. Vlès, 475
Nitrosophenylhydroxylamine (Cupferron), The Salts of, V. Auger, 379
Nitrotoluidine, Some Derivatives of, A. G. G. Leonard and Agnes Browne, 634
Noctiluca: Prof. C. A. Kofoid, 433; Pleurobrachia and Beroë, A Swarm of, in the Barrow Channel, A. Scott, 656
Noon Reflector, A, Prof. C. V. Boys, 117
Norfolk and Norwich Naturalists' Society, Transactions of the, vol. x., part 5, 115
North: America, Geodetic Survey in, 141; Atlantic Ocean, Meteorological Office Chart of the, February, 181; Stray Mines in the, Prince Albert de Monaco, 282; -East Ireland, An Analysis of the Palæozoic Floor of, with Predictions as to Concealed Coalfields, W. B. Wright, 368; Wales, A Handbook to the Vertebrate Fauna of, H. E. Forrest, 386
Northern: Fur-seal, Present Position of the, Dr. Evermann, 623; Polytechnic Institute, Re-establishment of the School of Rubber Technology at the, under the Directorship of Dr. P. Shidrowitz, 731
Nototherium: Skeleton Found in Tasmania of the, 559; H. H. Scott and C. Lord, 593
Nottingham, University College, Gift by Sir Jesse Boot, 665
Nova: Aquilæ, The Expanding Disc of, Dr. J. Lunt, 595; in Cygnus, Discovery of a, W. F. Denning, 838; in a, Spiral Nebula, Prof. Wolf, 213
Nuclear Constitution of Atoms, Sir Ernest Rutherford, 500
Nucleus, The Structure of the, 482
Nudity in India in Custom and Ritual, Dr. W. Crooke, 723

Obligation, Autonomy, and the Common Good, C. C. J. Webb, 249
Occultism, The Prevalence of, E. Clodd, 432
Oceanography and the Sea-fisheries, Prof. W. A. Herdman, 813
Officers: Seconding of, for Study at Universities, Prof. J. Wertheimer, 41; Training Corps, The; and the Universities, 349
Oil: and Colour Chemists' Association, Dr. R. S. Morrell elected President of the, 527; -engine Cycles, Claim as a Pioneer Inventor of, H. Akroyd Stuart, 499

Oils, Commercial, Vegetable and Animal. With Special Reference to Oriental Oils, I. F. Laucks, 132
Okefinokee Swamp, Georgia, F. Harper, 593
Oligochæta from the Lesser-known Parts of India and from Eastern Persia, Prof. Stephenson, 656
Optical: Instruments in Industry, 394; Projection, Lewis Wright. Fifth edition, re-written and brought up to date by R. S. Wright. (In two parts.) Part i., The Projection of Lantern Slides, 733
Optics and Mechanics of Precision, Review of, March and April, 725
Optophone: The, Dr. E. E. Fournier d'Albe, 295; of Dr. E. E. Fournier d'Albe and Prof. A. Barr, 722
Ordnance Survey Maps, New, Lt.-Col. W. J. Johnston, 312
Organic Compounds: Magnetic Properties of, Major A. E. Oxley, 243; The Identification of, the late Dr. G. B. Neave and Prof. I. M. Heilbron. Second edition, 774
Organisation of Scientific Work: Dr. W. Bateson; J. S. Gamble; Sir Ronald Ross, 6; Dr. E. J. Russell; Prof. A. C. Seward, 7; Sir Leonard Rogers, 292
Ornithological Notes from Norfolk, J. H. Gurney, 81
Oshima, A Study of, S. Tsuboi, 787
Ostrich: A Stalked Parapineal Vesicle in the, Prof. J. E. Duerden, 516; Study in South Africa, Prof. J. E. Duerden, 106
Ovamboland, The Kalahari and, Prof. E. H. L. Schwarz, 297
Ovum, The Fertilisation of the, 225
Oxford University: Abolition of Compulsory Greek at, 17; Sir Archibald E. Garrod appointed Regius Professor of Medicine in, 25; Prof. R. A. Sampson appointed Halley Lecturer for 1920, 56, 537; Dean Inge to deliver the Romanes Lecture on "The Idea of Progress," 155; Acceptance of Offer from E. Whitley towards the Endowment of a Professorship of Biochemistry; Donation towards the Extension of the Organic Chemical Laboratory from the British Dyestuffs Corporation, 313; Conferment of the Honorary Degree of Doctor of Letters upon Prof. T. Zammit; Dr. T. R. Merton granted the title of Professor, 440; Dr. B. Moore appointed Professor of Biochemistry; Gift by W. Morrison to the Bodleian Library, 731
Oxidation by Air of Ferrous Compounds, The Catalytic Action of Copper Salts on the, L. Maquenne and E. Demoussy, 699
Oxides: Alloys of, Mlle. S. Veil, 347; of Nitrogen, Improvements relating to the Commercial Production of, in Arc Furnaces, F. Gros, 283
Ozone in the Atmosphere, Occurrence of, J. N. Pring, 645

Palæogeography, A Study in, Prof. A. C. Seward, 223
Palæolithic Flint Implements found in the River Gravels of the South of England, J. Reid Moir, 146
Palestine, Establishment of a Department of Antiquities for, 785
"Panchromatism," Second Edition, 306
Panorpoid Complex, The, Additions to Part 3, Dr. R. J. Tillyard, 667
Pan-Pacific Scientific Congress, Forthcoming, 398
Paper-Making and its Machinery, R. W. Sindall, 480; Including Chapters on the Tub-sizing of Paper, the Coating and Finishing of Art Paper, and the Coating of Photographic Paper, T. W. Chalmers, 480
Parallax Work at the Sproul Observatory, Dr. Miller, 500
Parallaxes of Globular Clusters and Spiral Nebulæ, K. Lundmark, 215
Para Rubber-Tree, Diseases of the, Exhibition of, 86
Paris Academy of Sciences, Prof. A. Fowler elected a Corresponding Member of the, 52
Pastimes for the Nature Lover, Dr. S. C. Johnson, 774
Peat Resources of Ireland, The, Prof. P. F. Purcell, 791
Pellagra amongst Armenian Refugees at Port Said, R. S. White, 592
Pelletierine and Methylpelletierine, G. Tanret, 442
Pelton-Wheel Construction, P. Pitman, 625
Pencil Writing, Early, Characteristics of Pigments in, C. Ainsworth Mitchell, 12
Pensions, University Stipends and, 477
Pepys, Evelyn and Swift, Weather Notes of, in Relation to British Climate, Capt. C. J. P. Cave, 393
Percussion-Figures, Dr. B. G. Escher, 171
Periodicity in Weather and Crops, Sir William Beveridge, 370
Periwinkle, Life-History of the, Dr. W. M. Tattersall, 373
Petrographical Notes on Rocks from Deception Island and Roberts Island, etc., H. H. Thomas, 282
Petroleum: Geology, H. B. Milner, 608; Industry, Economics of the, R. S. Dickie, 369
Petrological Microscope, A New Model Rotating-Stage, W. A. Richardson, 570
Petrology for Students: An Introduction to the Study of Rocks under the Microscope, Dr. A. Harker, Fifth Edition, 99
Pharmacodynamic Experiences, Sub-epidermic, M. Ascoli and A. Fagiuoli, II., III., 844
Pharmacology, Practical, Prof. W. E. Dixon, 420
Pharmacy, Science and, Progress in, C. A. Hill, 659
Phenological Observations for the Year 1919, J. E. Clark and H. B. Adames, 442
Phenylpropines, The, Lespieau and Garreau, 699
Philæ, Decipherment of the Bilingual Inscriptions at, Dr. W. Max Müller, 592
Philippine: Hawksbill Turtle, Need of Protection of the, E. H. Taylor, 756; Plants, New or Noteworthy, E. D. Merrill, 146; Wasp Studies, Part I., S. A. Rohwer; Part II., F. X. Williams, 600
Philippines: Palms of the, Dr. O. Beccari, 180; Peoples of the, Prof. A. L. Kroeber, 420
Philosophies, Sir Ronald Ross, 414
Philosophy, A Forthcoming Congress of, 654
Photochimie, Etudes de, Dr. V. Henri, 640
Photographic: Almanac, The British Journal, and Photographer's Daily Companion, 1920, Edited by G. E. Brown, 67; Developing Agents, Dr. Seyewetz, 182; Images, The Nature of, Dr. C. E. Kenneth Mees, 307
Photography: Aircraft, in the Service of Science, H. Hamshaw Thomas, 457; and its Applications, W. Gamble, 740
Photosynthesis: in Fresh-Water Algæ, Prof. B. Moore and T. A. Webster, 26; in the Green Leaf, The Beginning of, G. E. Briggs, 89; The Photoplasmic Factor in, Dr. F. F. Blackman, 89
Physical: Chemistry, 129; Examination of Men of Military Age by National Service Medical Boards from November 1, 1917–October 31, 1918, Report upon the, 202; Fitness, The Assessment of, New Aspects in, Dr. F. G. Hobson, 812; Nature-Study, A Field and Laboratory Guide in, Prof. E. R. Downing, 675; Progress, Indices of, Dr. Lempriere, 26
Physico-chemical Analysis: A Method of, of Commercial Chlorobenzenes, F. Bourion, 379; Application of a New Method of, to the Study of Double Salts, D. Dubrisay, 634
Physics: Elementary, Selected Studies in, A Handbook for the Wireless Student and Amateur, E. Blake, 739; for Junior Technical Schools, A First Year, G. W. Farmer, 229; Institute of, Foundation of the, Sir Richard Glazebrook elected First President, 304; Measurements, A Handbook of, E. S. Ferry, O. W. Silvey, G. W. Sharman, Jun., and D. C. Duncan, 2 Vols, 193; Some Applications of, to War Problems, 237; The Ultimate Data of, Prof. G. Dawes Hicks, 446; Theoretical and Practical, 193
Physiological Symbiosis, Prof. Pierantoni, 756
Physiology: and National Needs, Edited by Prof. W. D. Halliburton, 286; of Farm Animals, 704; Useful, 286
Pigments in Early Pencil Writing, Characteristics of, C. Ainsworth Mitchell, 12
Pilot: -balloon Ascents, Methods of Computation for, J. S. Dines, 837; Balloons, High Rates of Ascent of, Dr. W. van Bammelen, 485; Soundings with, in the Isles of Scilly, Capt. Cave and J. S. Dines, 663; The Rate of Ascent of, J. S. Dines, 581
Piltdown Remains, The, P. T. de Chardin, 593
Pine, The Cluster, Dr. M. Grabham, 675
"Pink Disease" in the Philippines, H. A. Lee and H. S. Yates, 115

Planet GM, The New Minor, C. Sola, 595
Planetary Families of Comets, The, Prof. H. N. Russell, 467
Plant: -cell, Structure of the, and its Metabolism, P. A. Dangeard, 251; The Binucleate Phase in the, Dr. Agnes Arber, 90; Culture in Denmark, Prof. J. K. Ravn, 761; -forms, The Changes in, obtained experimentally, G. Bonnier, 539; Pests in the British Empire, Legislation in regard to, C. P. Lounsbury, 502; Protection Institute, Organisation in the U.S.A. of a, 687
Plants: Colouring Matters of, 139; Experiments with J. B. Philip, 805; Movements in, Experiments on, Sir Jagadis Chunder Bose, 305; Movements of, 416; Researches on Growth of, Sir Jagadis Chunder Bose, 615, 648; Resistance of, to Insect Attacks, H. A. Ballou, and others, 503; The Apparent "Growth" of, (and of Inanimate Materials), and of the Apparent "Contractility," Dr. A. D. Waller, 410; The Geography of, Dr. M. E. Hardy, 386
Platana of the Cape Peninsula, The, C. L. Herman, 700
Plating with Nickel of Aluminium and its Alloys, The, L. Guillet and M. Gasnier, 475
Plato's Atlantis in Palæogeography, W. D. Matthew, 667
Pleasure-Unpleasure: An Experimental Investigation on the Feeling-Elements, Dr. A. Wohlgemuth, 3
Pleistocene Glaciation of England, Some Features of the, G. W. Lamplugh, 58
Pliocene: Floras, A Comparative Review of, based on the Study of Fossil Seeds, Mrs. Eleanor M. Reid, 249; River, a Great, on the South Side of the Himalayas, Dr. G. E. Pilgrim, 836
Plumage: Bill, The, and Bird Protection, Sir H. H. Johnston; Prof. H. M. Lefroy, 168; Sir Herbert Maxwell; Prof. A. Dendy, 169; Dr. W. E. Collinge, 196; Prof. J. E. Duerden, 263; "Talked Out," 303; (Prohibition) Bill, Importation of, Second Reading Carried, 366
Plumbiferous Barytes from Shibukuro, Japan, Prof. R. Ohashi, 569
Poetry and Medicine, Prof. D'Arcy W. Thompson, 414
Pocillopora cespitosa and *Seriatopora subulata*, The Development of, A. Krempf, 380
Poles of Metallic Arcs, The Pressure upon the, including Alloys and Composite Arcs, W. G. Duffield, T. H. Burnham, and A. A. Davis, 121
Polynesian Origins, A New Theory of, Prof. R. B. Dixon, 763
Polysaccharides, The Hydrolysis of the, E. Hildt, 603
Pomology: Scientific and Systematic, 629; The Journal of, Nos. 1 and 2, 629
Population and Parenthood, Problems of (Being the Second Report of, and the Chief Evidence taken by, the National Birth-rate Commission, 1918–20), 543
Porcelain, etc., Measurements of the Expansion of Samples of, W. H. Souder and P. Hidnert, 181
Port Erin Biological Station, The, 179
Porto Rico: Scientific Survey of, and the Virgin Islands, N. L. Britton and C. P. Berkey, 147; The Earthquake at, on October 11, 1918, Prof. H. F. Reid and S. Taber, 276; The Geological History of, E. T. Hodge, 593; The Shells of, Miss C. J. Mawry, 593
Potassium, Influence of, on the Physiological Characters of *Sterigmatocystis nigra*, M. Moilliard, 347
Powders, The Properties of, Dr. T. M. Lowry and F. C. Hemmings, 217
Power: Knowledge and, 93; L. Bairstow, 135; F.O.I., Dr. J. W. Evans, 165
Precipitation in Japan, Effect of Topography on, Prof. Terada, 599
Pre-Glacial Floras, Two, from Castle Eden (Co. Durham), Mrs. Eleanor M. Reid, 249
Prehistoric: Man and Racial Characters, 153; Relationship of the Various Periods of, to the Great Ice Age, Prof. J. E. Marr, 153; Villages, Castles, and Towers of South-Western Colorado, J. W. Fewkes, 367
Pre-Palæolithic Man, J. Reid Moir, 289
Pressure on the Electrical Resistance and Thermo-electric Properties of Metals, Effects of, Dr. P. W. Bridgman, 529
Priapulus humanus taken by the Canadian Arctic Expedition, 1913–18, R. V. Chamberlin, 786
Primitive Functions, L. Tonelli, 251
Primula officinalis, etc., in the West of France, The Comparative Geographical Distribution of, Ad. Davy de Virville, 411
Privy Council, Sir T. Clifford Allbutt to be Sworn a Member of the, 590
Producer-Gas Plant for Power and Heating, Operating a By-product, W. H. Patchell, 148
Progress!: Sir E. Ray Lankester, 733; The Idea of, Dean Inge, 431; An Inquiry into its Origin and Growth, Prof. J. B. Bury, 733
Prominences, Observations of, J. and Mrs. Evershed, 340
Proper Motions, Search for, by the Blink Method, R. T. A. Innes, 759
Protein Requirement of Maintenance in Man, The, H. C. Sherman, 668
Proteins: The, 257; The Physical Chemistry of the, Prof. T. B. Robertson, 257
Protoplasm, The Components and Colloidal Behaviour of, Dr. D. T. MacDougal, 795
Psychological Tests in Industry, 673
Psychologies, Sir Ronald Ross, 414
Psychology: Applied, A Laboratory of, 305; from the Standpoint of a Behaviorist, Prof. J. B. Watson, 512; New Conceptions of, 363; of the Future, The ("L'Avenir des Sciences Psychiques"), E. Boirac; Translated and Edited with an Introduction by W. de Kerlor, 323; Social, An Introduction to, Dr. W. McDougall, Fourteenth Edition, 291; The New, and its Relation to Life, A. G. Tansley, 770; Vocational, A Laboratory of, 210
Psychotherapy, The Theoretic Basis of, 770
Public Health and Welfare, 151
Pulmonary Lesions determined by Blistering Compounds, A. Mayer, Guisysse, Plantefol, and Fauré-Fremiet, 604
Pygmies of Central Africa, The, H. Lang, 367
Pygmy Races of Man, The, L. R. Sullivan, 367
Pyruvic Acid, New Observations on the Biochemical Production of, A. Fernbach and M. Schoen, 251

Qualitative Analysis in Theory and Practice, Prof. P. W. Robertson and D. H. Burleigh, 705
Queensland Ironbark, A New Species of, R. H. Cambage, 732
Quintic Transformations and Singular Invariants, W. E. H. Berwick, 474

Rabbit, The, deprived of its Cæcal Appendix, regenerates this Organ by differentiation of the Extremity of the Cæcum, P. Portier, 347
Radio: Call Signal, A New, Major Shaughnessy, 690; -Diagnosis of Pleuro-Pulmonary Affections, E. Barjon, Translated by Dr. J. A. Honeij, 4; Research Board, O. F. Brown appointed Technical Officer to the, 463; Sub-Committees to assist the, 754
Radium: Facts, 435; for Curative Purposes, Reduction in the number of White Corpuscles in those handling, Mottram and Clarke, 400; Le, Interprétation et Enseignement de la Radioactivité, Prof. F. Soddy, Traduit de l'Anglais par A. Lepape, 805
Railways, Electrification of, Appointment of a Committee on the, 113
Rainbow Inside Out, A, C. O. Bartrum, 388
Rainfall and Land Drainage, Dr. Brysson Cunningham, 42
Ramsay Memorial Fellowships, Forthcoming Award of, 249
Rats: Destruction of, by Chloropicrin, G. Bertrand and M. Brocq-Rousseu, 27; Repressive Measures against, M. A. C. Hinton, 756
Rayleigh, The Late Lord, The Memorial to, 687
Rays, Tracing, through an Optical System, T. Smith, 473
Reactions started by a Primer, Some, E. Berger, 603
Reading, The Proposed University of, 88
Real Variables, The Commutativity of One-parameter Transformations in, A. C. Lunn, 667

Reduction of Error by Linear Compounding, W. F. Sheppard, 632
Reflex Action produced by the Irritation of the deeper Respiratory Tracts, A. Mayer, H. Magne, and L. Plantefol, 507
Refraction: and Dispersion of Carbon Dioxide, Carbon Monoxide, and Methane, C. and Maude Cuthbertson, 58; of Air for Wave-lengths, Measurements of the Index of, W. F. Meggers and C. G. Peters, 53
Regional Association, and the Civic Education League, Proposed Meeting of the, 376
Relativity: and Geometry, E. Cuningham, 350; and Hyperbolic Space, Prof. A. McAulay, 808; and Reality, Prof. R. A. Sampson, 708; Theory of Gravitation, The Central Differential Equation in the, Prof. A. R. Forsyth, 186
Religion and Culture: A Critical Survey of Methods of Approach to Religious Phenomena, Dr. F. Schleiter, 451
Reminiscences, H. Keeping, 624
"Renal Portal" System (Renal Venous Meshwork) and Kidney Excretion in Vertebrata, The, Prof. W. N. F. Woodland, 410
Renilla, The Phosphorescence of, Prof. G. H. Parker, 843
Research: Association for the Silk Industry, The, Approved, 591; for the Cutlery Industry, The, Approved, 623; Associations, Remuneration and Superannuation of Scientific Workers employed by, J. W. Williamson, 372; Defence Society, Annual Meeting of the, 557, 785; The Nature, Scope, and Difficulties of, Dr. W. L. Balls, 497
Respiration, Prof. W. J. V. Osterhout, 795
Respiratory: Endurance, The Index of, J. Amar, 59; Passages, The Reflexes provoked by Irritation of the, A. Mayer, H. Magne, and L. Plantefol, 443

REVIEWS AND OUR BOOKSHELF.

Agriculture and Horticulture:

Benson (O. H.), and G. H. Betts, Agriculture and the Farming Business, 35
Buller (Prof. A. H. R.) Essays on Wheat, 224
Frederiksen (J. D.), The Story of Milk, 229
Hall (Sir A. D.), The Soil: An Introduction to the Scientific Study of the Growth of Crops. Third edition, 384
Hedrick (U. P.), Manual of American Grape-growing, 674
Lloyd (S. L.), Mining and Manufacture of Fertilising Materials, and their Relation to Soils, 4
Mackenzie (K. J. J.), with a preface and chapter by Dr. F. H. A. Marshall, Cattle and the Future of Beef-production in England, 62
Newman (L. F.), and Prof. H. A. D. Neville, A Course of Practical Chemistry for Agricultural Students, Vol. i., 291
Rew (Sir R. Henry), Food Supplies in Peace and War, 326
Russell (Dr. E. J.), A Student's Book on Soils and Manures. Second edition, 130
Shanahan (Dr. E. W.), Animal Foodstuffs: Their Production and Consumption, with a special reference to the British Empire, 513
Simpson (J. T.), Hidden Treasure: The Story of a Chore Boy who made the Old Farm Pay, 36
Staward (R.), Practical Hardy Fruit Culture, 545
Wild (L. J.), Soils and Manures in New Zealand, 130
Wood (T. B.), and Dr. F. H. A. Marshall, Physiology of Farm Animals. Part i., General, Dr. F. H. A. Marshall, 704

Anthropology and Archæology:

Burrow (E. J.), The Ancient Entrenchments and Camps of Gloucestershire, 128
Farabee (W. C.), The Central Arawaks, 159
Harrison (Dr. H. S.), The Ascent of Man, 708
James (Rev. E. O.), An Introduction to Anthropology: A General Survey of the Early History of the Human Race, 384
Keane (Prof. A. H.), Man: Past and Present. Revised, and largely re-written by A. H. Quiggin and Dr. A. C. Haddon, 255
Kroeber (Prof. A. L.), Peoples of the Philippines, 420
Routledge (Mrs. Scoresby), The Mystery of Easter Island: The Story of an Expedition, 583
Schleiter (Dr. F.), Religion and Culture: A Critical Survey of Methods of Approach to Religious Phenomena, 451
Schmidt (P. W.), Die Gliederung der Australischen Sprachen: Geographische, bibliographische, linguistische Grundzüge der Erforschung der Australischen Sprachen, 707

Biology:

Agar (Prof. W. E.), Cytology: With Special Reference to the Metazoan Nucleus, 482
Bartsch (P.), Experiments in the Breeding of Cerions, 545
Boerker (Dr. R. H. D.), Our National Forests: A Short Popular Account of the Work of the U.S. Forest Service on the National Forests, 577
Borradaile (L. A.), A Manual of Elementary Zoology. Third edition, 804
Brook (A.), The Buzzard at Home, 746
Buchanan (Capt. A.), Wild Life in Canada, 426
Church (A. H.), Elementary Notes on Structural Botany; Elementary Notes on the Reproduction of Angiosperms, 162
Cockayne (Dr. L.), New Zealand Plants and their Story. Second edition, 707
Cook (Dr. M. T.), Applied Economic Botany: Based upon Actual Agricultural and Gardening Projects, 34
Coward (T. A.), The Birds of the British Isles and their Eggs. First series, 132
Crabtree (J. H.), Grasses and Rushes, and How to Identify Them, 805; Wonders of Insect Life: Details of the Habits and Structure of Insects, 651
Davies (J. H.), A Map of the World (on Mercator's Projection), having special reference to Forest Regions and the Geographical Distribution of Timber Trees: Timber Maps, Nos. 1 to 4, 577
Detmold (E. J.), Twenty-four Nature Pictures, 352
Doncaster (Prof. L.), An Introduction to the Study of Cytology, 190
Dymes (T. A.), The Nature Study of Plants in Theory and Practice for the Hobby-Botanist, 804
Ellis (Dr. D.), Iron Bacteria, 323
Ellis (G. S. M.), Applied Botany, 164
Fabre (J. H.), Translated by A. T. de Mattos, The Mason-Wasps, 291; The Story Book of Science; The Story Book of Birds and Beasts, 651
Fawcett (W.), and Dr. A. B. Rendle, Flora of Jamaica. Vol. iv., Dicotyledons: Families Leguminosæ to Callitrichaceæ, 738
Forrest (H. E.), A Handbook to the Vertebrate Fauna of North Wales, 386
Gamble (J. S.), Flora of the Presidency of Madras. Part iii., 36
Hardy (Dr. M. E.), The Geography of Plants, 386
Hiley (W. E.), The Fungal Diseases of the Common Larch, 639
Hudson (W. H.), Birds in Town and Country; The Book of a Naturalist, 651
Jenkins (Dr. J. T.), The Sea Fisheries, 397
Johnson (Dr. S. C.), Wild Fruits and How to Know Them, 774
Lillie (Prof. F. R.), Problems of Fertilisation, 225
Marshall (the late Prof. A. M.), and the late Dr. C. H. Hurst, A Junior Course of Practical Zoology. Ninth edition, revised by Prof. F. W. Gamble, 516
Matisse (G.), Action de la Chaleur et du Froid sur l'Activité des Etres Vivants, 161
Maulik (Prof. S.), The Fauna of British India, including Ceylon and Burma. Coleoptera. Chrysomelidæ (Hispinæ and Cassidinæ), 64
Mullens (W. H.), H. Kirke Swann, and Rev. F. C. R. Jourdain, A Geographical Bibliography of British Ornithology from the Earliest Times to the end of 1918. Part i., 353

Nicoll (M. J.), Hand-list of the Birds of Egypt, 674
Parkinson (Dr. W. H.), and H. D. Bell, Insect Life on Sewage Filters, 131

San Juan District, Porto Rico, The Geology of the, D. R. Semmes, 148
Sands, Stratified, and Gravels replaced by "Snow-white Granular Silica," W. H. Collins, 242
Saturn, Occultation of a Star by, 244
Savages of the Far Past, 384
Sawing Metals by Hand, Work done in, Ch. Fremont, 251
Saxon Remains, Supposed, Discovery of, in Windsor Great Park, Capt. Vaughan-Williams, 209
Scabiosine, A New Glucoside capable of Hydrolysis by Emulsion, Em. Bourquelot and M. Bridel, 187
Scandinavian Mountain Problem, The, O. Holtedahl, 633
Schaumasse Comet, 1920*b*, Discovery and Observations of, A. Schaumasse, 794
Scholarships, Plea for an Ampler Provision of, Dr. R. S. Clay, 23
Scholasticism, Science and, Prof. J. J. Walsh, 547; Dr. C. Singer, 548
School and University Training, Formation of a Consultative Council of the Overlapping of, 602; Celebrations, A First Book of, Dr. F. H. Hayward, 707; A Second Book of, Dr. F. H. Hayward, 804
Science: and Crime, 772; and Engineering, 258; and Life: Aberdeen Addresses, Prof. F. Soddy, 1; and Pharmacy, Progress in, C. A. Hill, 659; and Philosophy, Greek, Dr. C. Singer, 373; and Research in the Air Service 142; and Scholasticism, Dr. C. Singer, 127; Prof. J. J. Walsh, 547; Dr. C. Singer, 548; and Scientific Research in Medicine and Surgery, Sir Aston Webb, 304; and the Nation, Lord Sydenham, 468; and the New Army, 61; Col. E. H. Hills, 103; Prof. L. N. G. Filon; Prof. R. Whiddington, 133; Lt.-Col. E. Gold; Dr. C. S. Myers, 135; Prof. A. R. Richardson, 170; Col. K. E. Edgeworth, 233; C. S. Wright, 391; and Technology, The Imperial College of, 173; and Theology: their Common Aims and Methods, F. W. Westaway, 607; Applied and Industrial Research, J. W. Williamson, 387; Prof. F. Soddy, 422; Major A. G. Church, 423; J. W. Williamson, 518; Major A. G. Church, 547; Artillery, Sir George Greenhill, 268; Education and, in the Civil Service Estimates for 1920-21, 246; General, First Course, L. Elhuff, 352; History of, Courses on the, 279; in Medical Education, Prof. S. J. Hickson, 643; in the Elementary School,

the Teaching of, G. H. Trafton, 420; Museum, South Kensington, Col. H. G. Lyons appointed Director and Secretary to the, 463; the Geological Survey and Museum of Practical Geology, Reports on the, for 1919, 656; Practical for Girls: as Applied to Domestic Subjects, E. E. Jardine, 705; The Federation of, 317; The Story Book of, J. H. Fabre, 651

Scientific: and Technical Books, Sir R. A. Gregory, 41; Apparatus and Laboratory Fittings, C. Beck, 355; B. H. Morphy; C. Baker, 356; Bellingham and Stanley, Ltd.; W. Taylor; H. W. Ashfield, 357; Apparatus, British and Foreign, D. H. Baird, 390; J. W. Ogilvy, 424; J. S Dunkerly, 425; F. W. Watson Baker, 518; Prof. W. M. Bayliss, 641; Apparatus from Abroad, Prof. W. M. Bayliss, 293; Direction of Industrial Research, Major A. G. Church, 40; Method: Its Philosophy and its Practice, F. W. Westaway. New edition, 5; Publications, The Cost of, 285; Prof. W. A. Herdman; Prof. H. H. Turner, 326; E. B. Knobel; W. W. Bryant, 327; Prof. G. H. Hardy; Dr. A. B. Rendle, 353; Dr. C. S. Myers, 354; Dr. C. G. Knott, 425; Research, Dr. J. W. Evans, 358; and the Glass Industry in the United States, Dr. M. W. Travers, 9; Importance of Co-operative, E. B. Wedmore, 339; The Public Support of, Prof. F. Soddy, 309; Reunions at the Natural History Museum, Dr. G. F. H. Smith, 72; Societies, Conjoint Board of, Report for 1919, 343; Work, Expenses of, Major A. G. Church, 72; in India, The Organisation of, 565; Sir Thomas H. Holland, 452; Work: Its Spirit and Reward, Dr. G. J. Fowler, 387; Organisation of, Dr. W. Bateson; J. S. Gamble, Sir Ronald Ross, 6; Dr. E. J. Russell; Prof. A. C. Seward, 7; Sir J. C. Bose, 39; Sir T. H. Middleton, 103; Sir Leonard Rogers, 292

Scotland, The Economic Geology of the Central Coalfield of, 656

Scottish Shale Oil Scientific and Industrial Research Association, Approval of the, 210

Screw Gauges, Verification of, for Munitions of War, M. Cellerier; B. Powell, 184

Sea: and Sky at Sunset, Lt.-Col. K. E. Edgeworth; J. S. D., 358; -anemones, The Transplanting of, by Hermit Crabs, R. P. Cowles, 668; -birds: Their Relation to the Fisheries and Agriculture, Dr. W. E. Collinge, 172; Fisheries, Oceanography and the, Prof. W. A. Herdman, 813; The, Dr. J. T. Jenkins, 397; -waves, the Height of, J. Rouch, 219

Seed: Electrification, Experiments in, Sutton and Sons, 337; -wheat, the Treating of, for Bunt, 211

Seedlings which turn Green in the Dark, H. Coupin, 411

Seismological Observations at De Bilt, Report of the, for 1916, 276

Selous Memorial at the Natural History Museum, The, 504

Sensation and the Cerebral Cortex, Dr. H. Head, 363

Serum, Proteins of the, Separation of the, M. Piettre and A. Vila, 571

Service Chemistry, the late Prof. V. B. Lewes and Prof. J. S. S. Brame. Fifth edition, Sir T. E. Thorpe, 287

Sewage: Filters, Insect Life on, Dr. W. H. Parkinson and H. D. Bell, 131; Systems, Past and Present, A. J. Martin, 702

Shamanism among the Cahuilla Indians, Miss L. Hooper, 592

Sheep, the Fattening of, Application of the Food-unit System to, Prof. J. Wilson, 282

Sheffield: University, Dr. W. E. S. Turner appointed Professor of Glass Technology; J. Husband, Professor of Civil Engineering; Dr. Mellanby, Professor of Pharmacology; R. E. Pleasance, Demonstrator in Pathology, 601; Dr. R. B. Wheeler appointed Professor of Fuel Technology; D. Knoop, Professor of Economics, 665

Shell Flight, The Dynamics of, R. H. Fowler, 459

Shepherd's-purse, A Third Duplication of Genetic Factors in, Prof. G. H. Shull, 705

Shilluks' Belief in Medicine Men, The Rev. D. S. Oyler, 52

Sierra Leone, Pleistocene Movements of Elevation in, F. Dixey, 689

Silicate and Carbonate Rocks, Analysis of, W. F. Hillebrand, 836

Silicon Iron (Stalloy), The Magnetic Properties of, in Alternating Magnetic Fields of Low Value, A. Campbell, 473

Silver: Its Intimate Association with the Daily Life of Man, B. White, 774; The World's Production of, Report on, Prof. H. C. H. Carpenter and Prof. C. G. Cullis, 72

Simocephalus vetulus, Production and Transmission of an Environmental Effect in, H. G. Cannon, 538

Sky, the Blue, and the Optical Properties of Air, Lord Rayleigh, 584

Slag, a New Use for, 434

Sleeping Sickness Commission of the Royal Society, Reports of the, No. xvii., 663

Smithsonian, Lessons from the, 627

Smoke Nuisance, The, 471

Snowdon, Little Book About, H. V. Davis, 787

Social: Diseases, The, Tuberculosis, Syphilis, Alcoholism, Sterility, Dr. J. Héricourt. Translated, and with a final chapter, by B. Miall, 543; Service in Rural Areas, Sir Henry Rew, 731

Société Helvétique des Sciences Naturelles, Forthcoming Annual Meeting of the, 687

Society of Tropical Medicine and Hygiene, The, to be known in future as the Royal Society of Tropical Medicine and Hygiene, 526

Sodium Fluoride, The Usefulness of, Employed as an Antiseptic for the Preservation of Railway-sleepers, H. Devaux and H. Bouygues, 379

Softwoods, African, for Pulp Production, A. H. Unwin, 599

Soil: Cultivation, Physical Problems in, B. A. Keen, 438; Erosion, Observations on, W. Torrance, 434; Temperatures, F. L. West, N. E. Edlefsen, and S. Ewing; Capt. T. B. Franklin, 628; Effect of Weather Changes on, Capt. T. B. Franklin, 282; The, An Introduction to the Scientific Study of the Growth of Crops, Sir A. D. Hall. Third edition, 384

Soils: A Standard Book on, 384; Ammoniating Power of, Measure of the, R. Perotti, 844; and Manures, A Student's Book on, Dr. E. J. Russell. Second edition, 130; in New Zealand, L. J. Wild, 130

Solanaceæ, The Embryogeny of the, R. Souèges, 442, 475

Solar: Constant of Radiation, A New Method of Determining the, C. G. Abbot, 667; Chromosphere, Ionisation in the, M. N. Saha, 232; Eclipse, The Total, of 1918, June 8, Dr. Slipher, and others, 117; of May, 1919, The, Prof. L. A. Bauer, 311; Radiation Station, New, in Arizona, 726; Variation and the Weather, Dr. C. G. Abbot, 678

Solifugæ of South Africa, Survey of the, J. Hewitt, 275

Solvay, International Institute of Physics, Impending Resumption of the Work of the, 399

Somersetshire: Archæological and Natural History Society, Annual Meeting of the, Presidential Address to the, H. Balfour, 835

Sorby Research Fellowship, The, awarded to Dr. F. C. Thompson, 377

Sorosporella uvella, Experiments on, A. T. Speare, 310

Sound: -ranging as practised by the U.S. Army during the War, Prof. A. Trowbridge, 116

South: Africa, Ostrich Study in, Prof. J. E. Duerden, 106; African Entomophthoraceæ, Some, S. H. Skife, 507; America: In the Wilds of, Six Years of Exploration in Colombia, Venezuela, British Guiana, Peru, Bolivia, Argentina, Paraguay, and Brazil, L. E. Miller, 159; The Wilds of, 159; American Monkeys, External Characters of, R. I. Pocock, 218; -Eastern Union of Scientific Societies, Annual Congress of the, 530

Southampton, University College of, S. Mangham appointed Professor of Botany at the, 698

Southern Pine Association, Gift from the, for Forestry Work, 52

Space: and Time in Contemporary Physics: An Introduction to the Theory of Relativity and Gravitation, Prof.

M. Schlick. Rendered into English by H. L. Brose, 546; Time, and Deity: The Gifford Lectures at Glasgow, 1916-18, Prof. S. Alexander. 2 vols., 798
Spark Spectra of various Elements in Helium in the Extreme Ultra-violet, Prof. J. C. McLennan, and A. C. Lewis, 632
Species, Genera and, A. Mallock, 675
Spectra of Explosions, J. A. Anderson, 668
Spectral: Lines, Intensity of, Effect of a Magnetic Field on the, H. P. Waran, 379; Reflective Properties of certain Alloys, Preparation and Determination of the, R. G. Waltenberg and W. W. Coblentz, 212
Spectrometer, etc., Wave-length, Catalogue of Hilger's, 369
Spectropyrheliometer, A New, and Solar Measurements made with it, W. W. Coblentz and H. Kahler, 525
Spectroscopic Observations of the Gaseous Nebulæ, Certain Aspects of Recent, W. H. Wright, 842
Spectrum: An Experiment on the, Dr. R. A. Houstoun, 421; Certain Antagonistic Properties of various Regions of the, G. Le Bon, 571
Sphenodon punctatus, Development of the Auditory Apparatus in, F. J. Wyeth, 26
Spherical Conductors, The Capacity Coefficients of, A. Russell, 57
Sphexapata (*Miltogramma*) conica, Notes on the Habits of the Tachinid Fly, O. H. Latter, 614
Spica, Conjunction of Mars with, 340
Spiral: Compensator, The, and New Problems of the Mechanics of Regulation, J. Drach, 443; Nebulæ, Globular Clusters and, The Parallaxes of, K. Lundmark, 215
Spirit Levelling, Systematic Error in, J. H. Cole, 409
Spiritual Pluralism and Recent Philosophy, C. A. Richardson, 773
Spitsbergen, The Discovery of, Dr. F. Nansen, 210
Sponges: Dr. G. P. Bidder, 441; of Ireland, the Freshwater, Miss Jane Stephens, 474
Spores and Plant-life in Deep Caves, The Carrying Power of, Edith A. Stoney, 740
Spraying of Trees, Injury to Foliage by the, 211
Sproul Observatory, Parallax Work at the, Dr. Miller, 500
Standard Time in Finland, H.R., 145
Standing Stones at Duddo, The, Capt. W. J. Rutherford, 623
Star: A, with a Large Proper Motion, F. Kromm, 282; Clusters, Dr. H. Shapley, 54; Occultation of a, by Saturn, L. J. Comrie, 22
Stars: Double, J. Jackson, 436; The Masses of the, Prof. H. N. Russell, 500; Total Light of the, P. J. Van Rhijn, 54
State: Museums and the, Prof. E. W. MacBride; Prof. J. W. Gregory, 68; Dr. F. A. Bather; Dr. W. E. Hoyle, 69; W. G. Wagner, 70; Sir E. Ray Lankester; Prof. J. Stanley Gardiner, 101; Dr. W. M. Tattersall, 102; F.R.S., 136; The, and the National Museums, 29
Statics, School (School Mechanics, Part. I.), W. G. Borchardt, 163
Statistics, Applied, 470
Steel: Ingot, The Macrographic Study of the Propagation of Cooling in the Interior of a, starting from its solidification, Descolas and Prétet, 411; Ingots, the Minute Fissures in, G. Charpy, 27; Nickel, The Anomaly of Elasticity of the, C. E. Guillaume, 699; The Elasticity of Torsion of, with a high proportion of Chromium, P. Chevenard, 699; Special Alloy, in the Construction of Bridges, The Economical Use of, J. A. L. Waddell, 699; The Resistance of, to Cutting by Tools, Ch. Fremont, 187
Stelar: Facts, New, and their bearing on Stelar Theories for the Ferns, J. M'Lean Thompson, 250
Stellar: Dynamics, Problems of Cosmogony and, J. H. Jeans, 31; Spectroscopy at the Detroit Observatory, 244; Substance, The Wasting of, Prof. F. W. Very, 276
Stereochemistry, Prof. A. W. Stewart. Second edition, 129
Stewart Prize of the British Medical Association, The, awarded to Dr. Harriette Chick, 432
Stipends and Pensions, University, 477
Stone: Implements of Palæolithic Type Throwing Light on the Method of Manufacture in South Africa, Dr. L. Péringuey, 699; Mould, A Curious, Mrs. M. E. Cunnington, 497; Statues, The Island of, Sir Everard im Thurn, 583; Worship, A Curious Case of, H. A. MacMichael, 115
Stonehenge, Restoring to a Position of Safety the Stones of, 209
Stonyhurst: College: Observatory, Report and Notes on, 1919, Rev. A. L. Cortie, 624; Observations, 1919, Rev. A. L. Cortie, 789
Storm-petrel, Nesting Habits of the, A. Gordon, 20
Strand-loopers, Dr. L. Péringuey, 558
Strasbourg University, Opening Address at Installation of the Chair of Mineralogy in, Prof. G. Friedel, 368
String, An Experiment on a Piece of Common, G. F. C. Searle, 474
Sublimates produced by Metalloids and Metals Volatilised by the Blowpipe, Method for Collecting and Characterising the, Ad. Braly, 219
Submarine; Explosions, The Pressure-wave thrown out by, H. W. Hilliar, 313; Warfare of To-day, Lt. C. W. Domville-Fife, 36
Sugar: -beet during the War, The, E. Saillard, 571; Production in England, Possibilities of, 434; Cultivation in India, Dr. W. E. Brenchley, 840
Sulphuric Ions: Detection of Masked, in Complex Compounds, R. Job and G. Urbain, 283; in Complex Salts, the Differentiation of Masked and Apparent, A. Kling and D. Florentin, 379
Sumatran Hare (*Nesolagus Netscheri*), The, E. Jacobson and C. B. Kloss, 115
Summer, The Weather of the Present, 837
Sumner Line: The, or Line of Position as an Aid to Navigation, Prof. G. C. Comstock, 552; Lines in Navigation, Use of, Capt. T. H. Tizard, 552; Prof. G. C. Comstock; Capt. T. H. Tizard, 742; Dr. J. Ball, 806
Sun: as a Weather Prophet, The, 839; Mercury, and Venus, Cape Observations of the, 183; Meteorological Influences of the, and the Atlantic, Prof. J. W. Gregory, 715; Observations of the, made at the Lyons Observatory, J. Guillaume, 218; 251
Sundial giving Legal Time throughout the Year, A, Ch. Gautier, 506
Sunlight and the Life of the Sea, Dr. B. Moore, E. Whitley, and T. A. Webster, 90
Sunshine in the United States, J. B. Kincer, 791
Surveying: W. N. Thomas, 801; Principles and Practice of, Lt.-Col. H. S. Winterbotham, 801
Survival: A Theory of the Mechanism of, The Fourth Dimension and its Applications, W. W. Smith, 484
Swanley Horticultural College, Proposal to allot a Treasury Grant for the, 472
Swansea: University College, Prof. C. A. Edwards appointed Professor of Metallurgy, Dr. J. E. Coates Professor of Chemistry, Dr. E. A. Evans Professor of Physics, Lt.-Col. A. R. Richardson Professor of Mathematics, Dr. A. E. Trueman Lecturer in Geology, E. E. Hughes, Lecturer in History, 6 5; The Laying of the Foundation-stone by the King, 665 Grants to, by the Treasury, 841
Swift, Evelyn, Pepys, and, Weather Notes of, in Relation to British Climate, Capt. C. J. P. Cave, 393
Syme, The David, Prize awarded to F. Chapman, 496
Symmetrisable Functions and their Expansion in Terms of Biorthogonal Functions, J. Mercer, 632
Synapsis: Studies on, II., L. T. Hogben, 539; The Problem of, L. T. Hogben, 570
Synchytrium endobioticum (Schilb.), Perc., Life-history and Cytology of, Miss K. M. Curtis, 346
Synthetic Ammonia, The Manufacture of, and Production of Nitrates, 312

T.N.T., Products of Detonation of, Prof. C. E. Munroe, 795
Tanks: and Scientific Warfare, 702; in the Great War, 1914-1918, Brevet-Col. J. F. C. Fuller, 702
Tannins from Wattle-bark, Extraction of, 724

Tasmanian Mammals, Living and Extinct, Studies of. Part. ii., H. H. Scott and C. Lord, 796
Teachers in the U.S.A., The Supply and Remuneration of, 731
Technical: Colleges and the Universities, The Necessity for Close Co-operation Between, Principal C. Coles, 728; Education and Mind Training, E. L. Rhead, 439; Institutions, Association of, Annual General Meeting of the, 22; 727; Libraries and Intelligence, Major W. E. Simnet, 505; Library, The, R. Borlase Matthews, 505; *Review*, Retirement of Major W. E. Simnett from the Editorship and Direction of the, 722; Schools and their part in Adult Education, A. Mansbridge, 23
Techno-Chemical Receipt Book, Compiled and Edited by W. T. Brannt and Dr. W. H. Wahl, 739
Telephonic Transmission: Theoretical and Applied, J. G. Hill, 418
Telephony and Telegraphy, Multiplex, over Open-circuit Bare Wires laid in the Earth or Sea, Gen. Squier, 467; Wireless, Prof. W. H. Eccles, 519; without Wires, P. R. Coursey, 5
Telephotography, A Note on, A.B., 488
Telescope, The Optimum Magnification of a, M. Battestini, 443
Telescopes, Increasing the Photographic Power of, Dr. Shapley, 625
Tempel's Comet: Return of, 436; 560; M. Fayet, 789; P. Chofardet, 794
Temperature: Curve, The Daily, Prof. L. Becker, 282; Life and, 161; The Influence of, on the Rigidity of Metals, A. Mallock, 631; Variations at 10,000 ft., C. K. M. Douglas, 614; in the North Atlantic Ocean and in the Atmosphere, Drs. B. Helland-Hansen and F. Nansen, 715
Terra Sigillata, Introduction to the Study of, Dr. F. Oswald and T. D. Price, 240
Terraces in Chalk Districts, The Mode of Formation of, L. Gentil, 315
Terre et des Planètes, L'Origine des formes de la, E. Belot, 559
Tetanus during the Great War, Prevention of, Major-Gen. Sir David Bruce, 785
Tetrahedra, Generation of Sets of Four, mutually Inscribed and Circumscribed, C. V. H. Rao and Prof. Baker, 379
Textile: Industries and Technical Education in Canada and the United States, 789; Research in, 118; Students, Chemistry for, B. North, assisted by N. Bland, 382
Therapeutic Substances offered for Sale, Appointment of a Committee Upon, 273
Thermionic: Valve, The, in Wireless Telegraphy and Telephony, Prof. J. A. Fleming, 716; Valves, The Development of, for Naval Uses, B. S. Gossling, 559
Thermo: -couples, Construction of, by Electro-deposition, W. H. Wilson and Miss T. D. Epps, 842; -electricity, Recent Progress in, Prof. C. A. F. Benedicks, 409
Thermostatic Metal, 793
Thompson: Life and Letters of Silvanus P., A. A. Campbell Swinton, 448; Silvanus Phillips, D.Sc., LL.D., F.R.S., His Life and Letters, J. S. and H. G. Thompson, 448
Thrush, The First Act of a Young, Honor M. M. Perrycoste, 456
Thunder and Lightning at Kimberley, Some Statistics of, J. R. Sutton, 507
Thunderstorms of May 29, The, and the Louth Disaster, 468
Tidal: Friction and the Lunar and Solar Accelerations, Dr. H. Jeffreys, 403; in Shallow Seas, H. Jeffreys, 632; Motion in the Irish Sea: Its Currents and its Energy, R. O. Street, 632; Power, 427
Tides in Landlocked and Border Seas, Bays, and Channels, Dr. A. Defant, 466
Timber: Exhibition, The Empire, A. L. Howard, 691; Map, Nos. 1 to 4, J. H. Davies, 577
Timbers Grown in France, Forthcoming Researches upon, 722
Time: and Latitude, Methods of Determining, C. Puente, 213; -reckoning of the North American Indians, 75
Tin: and Antimony, The Separation of, A. Kling and A. Lassieur, 442; Ores, G. M. Davies, 193
Tissues, Resistance of, to Light and Ultra-violet Rays, L. Vignon, 500
Topography, Effect of, on Precipitation in Japan, Prof. Terada, 599
Toronto University: Dr. V. J. Harding appointed Professor of Pathological Chemistry in, 537; the Appointment of Prof. A. T. De Lury as head of the Department of Mathematics, 762
Torquay Natural History Society, Journal of the, Vol. II, No. 6, 788
Total Solar Eclipse of September 20, 1922, The, A. R. Hinks, 84
Toxines et Antitoxines, M. Nicolle, E. Césari, and C. Jouan, 67
Trade Routes of the British Empire in Africa, G. F. Scott Elliott, 274
Trans-African Flight, The Recent, Lt. L. Walmsley, 624
Transport, Some National Aspects of, Lord Montagu of Beaulieu, 469
Tree: Diseases, Manual of, Dr. W. H. Rankin, 577; -growth, Climatic Cycles, etc., Prof. Douglass, 562
Trichodynamics, Dr. W. Lawrence Balls, 777
Trioxymethylene: in Powder, The Use of, for the Destruction of the Larvæ of Mosquitoes, E. Roubaud, 604; The Mode of Action of Powdered, on the Larvæ of Anopheles, E. Roubaud, 667
Trobriand Islanders, The Economic Pursuits of the, Dr. B. Malinowski, and others, 564
Tropical: Agriculture, A College of, 153; Control of Australian Rainfall, E. T. Quayle, 152; Departments of Agriculture, with Special Reference to the West Indies, Sir Francis Watts, 344; Medicine, 33
Tsetse-Fly Problem, The, R. W. Jack, and others, 503
Tubercle Bacillus: Culture of the, on a Medium of Autolysed Yeast, R. Sazerac, 795; The Chemical Composition of the, A. Goris, 604
Tuberculosis, particularly in connection with the War, 558
Tungsten: and the Oxides of Tungsten, Reversible Reactions of Water on, G. Chaudron, 411; Preparation and Uses of, in Incandescent Lamp Filaments, etc., A. B. Searle, 339
Turbine Steels, The Mechanical Properties of, Dr. W. H. Hatfield and H. M. Duncan, 148
Turin Academy of Medicine, Award of the Riberi Prize to Prof. G. Vanghetti, 557
Twins, Influence of the Male on the Production of, Dr. C. B. Davenport, 755
Tycho Brahe, Dr. J. K. Fotheringham, 672
Tychonis Brahe Dani Opera Omnia, Edidit, I. L. E. Dreyer. Tomus VI, 672
Typhus Fever, 81

Ultra-Violet, Extreme, Some New Spark Spectra in the, L. and E. Bloch, 27
Union Observatory, The, Johannesburg, Circular No. 17, 759
U.S.A.: Increased Demand for Collegiate Education in the, 731; Army, Psychological Examining and Classification in the, Dr. R. M. Yerkes, 705; Bureau of Mines, Dr. F. G. Cottrell nominated as Director of the, 432; Commercial Marbles of the, Physical and Chemical Properties of, D. W. Kessler, 181; Engineering Research in the, A. P. M. Fleming, 598, General Education Board, Appropriations by the, 602; Glass Industry in the, Scientific Research and the, Dr. M. W. Travers, 9; National Academy of Sciences, F. D. Adams, M. E. C. Jordan, F. A. L. Lacroix, H. K. Onnes, Sir David Prain, and S. R. y Cajal elected Foreign Associates of the, 463; National Food Consumption in the, Prof. R. Pearl, 597; National Research Council, Appointment of a Committee on Eugenics, 240; Election of Chairman of Divisions of the, 754; Election of Officers of the, 526; Prof V. Kellogg, 332; Statistics of School Systems in the, for 1917-18, 841; Sunshine in the, J. B. Kincer, 791

Universe, The Structure of the, Prof. W. D. MacMillan, 789
Universities: and the Excess Profits Duty, 686; Research and Brain Waste, Prof. J. C. [illegible], 639; The, and the Army, 157; F. J. M. Stratton, 234; The Officers Training Corps and the, 349
University: and Higher Technical Education, 509; Benefactions, The Permanent Value of, Prof. Karl Pearson, 501; College, London, the Engineering School of, Scheme for Extension of, Prince Arthur of Connaught, and others, 113; College of South Wales and Monmouthshire, J. W. Scott appointed Professor of Logic and Philosophy in the, 537; Extension, Public Discussion and Information Service of, 762; Grants, 701; Sir M. E. Sadler, 740; Principal C. Grant Robertson, 774; Prof. W. H. Perkin, 805; of California Publications. Publications of the Lick Observatory. Vol. xiii., 489; of London: The, A Great Opportunity. 381; The, Government Offer of a Site, H. A. L. Fisher, 404; Problem, The, Sir E. Sharpey Schafer, 698; Stipends and Pensions, 477; G. W. O. H., 582; Teachers, Position of, in Relation to the Teachers (Superannuation) Act, 89; Women, First Conference of the International Federation of, 569, 663
Upper Air, Investigations of the, Dr. van Everdingen; Capt. Cave and J. S. Dines, 663
Uranyl Salts, The, Fluorescence and Absorption Spectra of, E. L. Nichols, H. L. Howes, and others, 498

Vacuum Arcs, The Use of, for Interferometry, J. Guild, 842
Valencies, Partial, The Conjugation of, Prof. R. Robinson, 346
Vapeur des Mélanges de Liquides: La Tension de, L'Azéotropisme, Dr. M. Lecat. Première Partie, 129
Vapour Densities, Calculation of, R. G. Durrant, 742
Vegetation of the Land, The Origin of the, Prof. A. C. Seward, 250
Venereal: Disease, Disinfection against, 834; Diseases, Portsmouth Borough Council and Prevention against, 335; Special Report on the Prevention of, Dr. A. M. Fraser, 114; Problem, The, E. T. Burke, 543
Verneuilina polystropha, Reuss, An Experimental Study of the Foraminiferal Species, and some others, E. Heron-Allen and A. Earland, 282
Vertebrate: Fauna of North Wales, A Handbook to the, H. E. Forrest, 386; Life in the Late Paleozoic in North America, The Environment of, Prof. E. C. Case, 223
Vibrating System, Maintenance of a, by Means of a Triode Valve, S. Butterworth, 842
Vibrations, Notes on the Theory of, W. J. Harrison, 473
Victoria History of the Counties of England, Issue in Parts of the, 305
Vinci, Leonardo da, E. McCurdy, 307, 340
Vine, Cultivation of the, in America, V. G. Jackson, 674
Viscometer, A Simple, A. G. M. Michell, 344
Viscosity of Colloidal Solutions, The, P. Barry, 539
Viscous Retrogression, Torsional, An Example of, C. Barus, 667
Vision, The Physiology of, with Special Reference to Colour Blindness, Dr. F. W. Edridge-Green, 575
Vital Statistics: An Introduction to the Science of Demography, Prof. G. C. Whipple, 131
Vitamines: for the Culture of Bacteria, R. Legroux and J. Mesnard, 315; in Clinical Medicine, The Present Position of, Prof. F. Gowland Hopkins, 722; in their Relation to Health, Col. McCarrison, 557; Necessary to the Development of Plants? Are, A. Lumière, 795; The Chemical Isolation of, C. M. Myers and C. Voegtlin, 667
Vocal Notes, Photographs of Seven, Dr. W. Perrett, 39
Volcanic Rocks in the Anglo-Egyptian Sudan, Dr. G. W. Grabham, 199
Volumetric Testing of Scientific Glassware, 120

Waage's Phytochemical Synthesis of Phloroglucin from Glucose, Dr. M. Nierenstein, 391
War: History of the Great, based on Official Documents. Naval Operations. Vol. i., Sir J. S. Corbett, 546; Problems, Some Applications of Physics to, 237
Warble-flies, Lateral Spiracles in the Larvæ of, Prof. G. H. Carpenter and F. J. S. Pollard, 835
Warlike States, The Origin of, W. J. Perry, 442
Washington, Ambassador Extraordinary and Plenipotentiary in, Sir Auckland C. Geddes appointed, 17
Wasps, W. F. Denning, 328
Water: -chambers, The Permanent *Régime* in, C. Camichel, 314; Power Resources Committee, Second Interim Report of the, 556, 705; Power Development, Canadian, L. G. Dennis, 311; Resources, The Control of, 705; Supply Papers of the United States Geological Survey, 434; Supply, Woods and, Dr. H. R. Mill, 158
Wave: -length of the Oscillations Generated by an Ionic Valve due to Changes in Filament Current, Variation of, J. H. Vincent, 121; -lengths of a Line of the Cyanogen Band in the Light of the Sun and that of a Terrestrial Source, Comparison of the, A. Perot, 794; -motion in a Deep Canal, Integration of the Equation of, H., U. Cisotti, 843
Waves, Growth of, A. Mallock, 777
Wealden Flint Culture from pre-Palæolithic Times, Evolution of, H. Morris, 431
Weather: and Climate of the British Isles and North-west Europe, Practical Exercises on the, W. F. Stacey, 133; and Crops, Periodicity in, Sir William Beveridge, 370; Changes, Effect of, on Soil Temperatures, Capt. T. B. Franklin, 282; Conditions, Local, at Mullion, Cornwall, Lieut. N. L. Silvester, 281; Forecasts and Meteorology, A. Mallock, 580; Notes of Evelyn, Pepys, and Swift in Relation to British Climate, Capt. C. J. P. Cave, 393; of 1919, The, 243; of the Spring Season, The, 498; Prediction, Utilisation of Cirrus Clouds for, G. Reboul and L. Dunoyer, 251; Solar Variation and the, Dr. C. G. Abbot, 678
Weights and Measures, British and Metric Systems of, M. E. Yeatman, 355; A. S. E. Ackermann, 456
Welfare Work, 55
West: Bromwich Municipal Technical Institute, E. Rawson appointed Principal of the, 698; Indies, Agricultural Development in the, 344; Distribution of Littoral Echinoderms of the, H. L. Clark, 279; Report of the Tropical Agricultural College Committee, 153; The Geology of the, 24
Western: Australia, A Coloured Geological Map of, 498; Royal Society of, Journal and Proceedings of the, 1918-19, 559; The Aborigines of, G. O. Neville, 248; Greece, The Hydrocarbon Zone of, C. A. Kténas, 251
Whale, Sperm, Two Embryos of the, Dr. F. E. Beddard, 275
Whales Frequenting South African Waters, Dr. L. Péringuey, 507
Wheat: and Wheat-growing, Dr. E. J. Russell, 224; Essays on, Prof. A. H. R. Buller, 224
Wild Life in Canada, Capt. A. Buchanan, 426
Will? Is there a General, M. Ginsberg, 155; The Freedom of the, The Zoroastrian Doctrine of, Prof. A. V. W. Jackson, 763
Wind at Kimberley, A Possible Lunar Influence upon the Velocity of the, J. R. Sutton, 700
Wines, Blue *Casse* of, Treatment of the, A. Piedallu, P. Malvezin, and L. Grandchamp, 442
Wireless: Licences for Experimental Work, The Post Office and, 80; Messages from Paris and Slough, 80; Signals, Mars and, 276; Station for Astronomy, Central, Major W. J. S. Lockyer, 454; Telegraphy, Device for Obviating the Use of High Voltages in, L. M. Hull, 624; Longitude by, Prof. Sampson, 370; to America, Reduction of Charges for, 18; and Telephony: First Principles, Present Practice, and Testing, H. M. Dowsett, 483; for Use in the Army, 528; The Thermionic Valve in, Prof. J. A. Fleming, 716; Telephony, Prof. W. H. Eccles, 519; Duplex, Application of, to Aircraft, Capt. P. P. Eckersley, 154; in Aeroplanes, Major C. E. Prince, 55; to and from Aeroplanes, and Wireless Direction-finding Apparatus, Demonstration of, 149; Time-signals, Eiffel Tower, Prof. R. A. Sampson, 265; Transmission of Photographs, M. J. Martin. Second

edition, 451; Weather Forecasts for London and South-East England, 465
Wood, Treatment and Preservation of, 401
Woods and Water Supply, Dr. H. R. Mill, 158
Woolwich: The Research Department, Sir Robert Robertson, 710, 743; Exhibits of the, at the Imperial War Museum, 622
Wound-shock, The Circulating Blood in Relation to, Prof. W. M. Bayliss, 9
Wright, Wilbur, Unveiling a Statue to the Memory of, 654

Xenolithic Tertiary Minor Intrusions in the Island of Mull, Certain, Dr. H. H. Thomas, with Chemical Analyses by E. G. Radley, 473
Xenopus laevis, The Reflex Times in, W. A. Jolly, 699
X-ray: Spectra, The Fine Structure of, M. de Broglie, 475; Tube Stands, Manipulation and Precision in Adjusting, 625
X-rays: of the L Series, The Intensities of, D. L. Webster, 667; The Examination of Materials by, A General Discussion held by the Faraday Society and the Rontgen Society, April 29, 1919, 132

Year-book of the Scientific and Learned Societies of Great Britain and Ireland, The, Thirty-sixth Annual Issue, 586
Yorkshire Summer School of Geography, Forthcoming, 185

Zeeman Effect in Furnace Spectra, The, A. S. King, 529
Zinc: and Copper, The Constituents formed by Reciprocal Penetration of, at a Temperature where One of the Two Metals and all their Alloys are in the Solid State, H. Weiss, 699; and its Alloys, Dr. T. NATURE

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE

*"To the solid ground
Of Nature trusts the mind which builds for aye."*—WORDSWORTH.

THURSDAY, MARCH 4, 1920.

Knowledge and Understanding.

Science and Life: Aberdeen Addresses. By Prof. Frederick Soddy. Pp. xii+229. (London: John Murray, 1920.) Price 10*s.* 6*d.* net.

> Hear, Land of Cakes and brither Scots,
> Frae Maidenkirk to Johnny Groat's;
> If there's a hole in a' your coats,
> I rede ye tent it;
> A chiel's amang ye takin' notes,
> And, faith, he'll prent it.

PROF. SODDY, who has recently removed from the chair of chemistry in the University of Aberdeen to the newly created Lee's professorship of inorganic and physical chemistry in the University of Oxford, is well known throughout the scientific world by reason of his work in connection with the subject of radio-activity, to which he has made very important contributions. But it was not suspected, at least generally, that from his northern post of observation he was finding so many holes in the coats of the inhabitants of that part especially, and of the institutions of the country generally, and that he would "prent it." Yet here is a volume which bears as sub-title "Aberdeen Addresses," the delivery of which must have caused many of his "unco' guid" neighbours to sit up and perhaps *furieusement à penser.* But, as the old clerk in "Silas Marner" said: "Where's the use o' talking? You can't think what goes on in a cute man's inside."

We must all agree with the author in the view that "the times seem to call for outspokenness, if one has anything to say, rather than persuasive propagandism and time-serving compromise. It may be recalled that scientific men have, for nearly a century, pointed out the dangers to the nation of the traditional school and university training, disastrous especially in that it embraces even those who are to be its rulers and statesmen." So Prof. Soddy has spoken out with a voice which is bound to be heard even by those who, having no ears to hear, or understanding to learn, cannot help catching the echoes of this new trumpet-call.

The essays may be broadly divided into two groups, of which one contains an exposition of the marvellous disclosures concerning the physical constitution of matter which have absorbed the concentrated attention of so many physicists during the last twenty years, while the second group, addressed to various audiences, shows the bearing of modern scientific discovery on the philosophies hitherto prevalent.

Let us glance first at the former set of essays. For nearly a century the atomic theory of Newton and Dalton had been accepted by chemists as the almost undisputed basis of their theoretical conceptions, and for all ordinary chemical phenomena the atom is still the fundamental unit of mass. Views as to the nature of the atom and its constitution now assume a different form. It is as though an observer, looking along a street, having formerly supposed each house to consist of a solid mass of bricks, now finds out that each contains many chambers and inhabitants capable of moving about. This knowledge has been obtained in two ways. By bombardment the constituent materials and inhabitants have been distributed in various directions, and in a strange, unaccountable way the inhabitants of certain houses escape from them carrying away portions of the fabric, which is thus gradually led to tumble down. The metaphor can be carried no farther, but is sufficient to remind the reader of the conceptions gradually introduced as the result of experimental work carried on first by Crookes, and later especially by Sir Joseph Thomson, and, on the other hand, by the discoveries of

Becquerel and the Curies in connection with radio-activity.

Prof. Soddy has been associated with research on radio-activity since 1901, when, in Sir Ernest Rutherford's laboratory in Montreal, he joined in framing the idea which attributes radio-active change to the spontaneous disintegration of the atom. Later, in conjunction with Ramsay, he proved that the α-particles escaping from radium are electrified atoms of helium. In 1913 he also traced, simultaneously with other observers, the nature of the successive changes in radio-active matter which ultimately lead to the production of non-radio-active elements, of which the best-known case is lead. The whole story is told in a condensed form in several of the essays in this volume, and it could not be told better. Those who are interested in such subjects should obtain the book and read it.

Turning, now, to the remainder of the contents of this volume, so many questions are touched on of which many would be regarded as debatable that it seems probable that readers will be divided into two camps, those who would cordially approve and support the views set forth, and those, chiefly the orthodox, who would deeply resent the attitude and conclusions of the writer. The first article, entitled "Science and Life," deals with the influence which scientific discovery has exercised on the conditions of modern life, seen from various points of view, and contains little that is seriously controversial. There are, of course, passages which seem a little over-enthusiastic—*e.g.* the statement that, "if not yet, some time in the future, the synthesis of food from the material constituents and any form of available energy will probably become possible"—but the review given of the sources of energy in Nature is useful as popular instruction. The author's remarks on the relations of brains, labour, and capital seem rather to belong to the views likely to find expression at the meetings of a young men's debating society, though it is certainly true that "the exploiters of the wealth of the world are not its creators," and is likely to remain so until human nature undergoes a profound change. A similar remark might be made on the question which occurs in the second article: "Physical force, the slave of science, is it to be the master or the servant of man?"

Of course, Prof. Soddy has a good deal to say on the subject of education. He is an experienced and distinguished teacher, but in one direction he seems to overlook the necessity for clearly differentiating the kind of general education which must necessarily be provided wholesale for the great majority, and that which should be adapted to the exceptional youth, the genius, that *rara avis* for whom is wanted more in the shape of opportunity than in direct instruction along lines which may or may not be useful to him. The great difficulty in regard to this kind of student is to recognise his qualities early enough. In connection with the continued appropriation of more than their due share of scholarships, emoluments, and facilities of all kinds by the authorities and powers which claim to represent humanist interests at the schools and universities, everyone concerned with such matters remembers Prof. Soddy's criticism of the action of the executive committee of the Carnegie Trust for the Universities of Scotland in January, 1918, and the inadequate reply thereto. The whole of the relevant papers are added to this volume in a series of appendices A, B, and C.

Many people will find the lecture given to the Aberdeen University Christian Union on "Matter, Energy, Consciousness, and Spirit" among the most startling of the utterances contained in this book. There are still many serious religious persons who find the almost universal abandonment of the Mosaic account of Creation and of so many of the Hebrew legends disturbing to the whole of their Christian faith and subversive of all religion. But the religious reader may get some comfort from this chapter if he will read it thoughtfully and with prejudice discarded as much as possible. Truth in the realm of science is of a quality and nature quite its own, and the man of science who frames a hypothesis does so in the knowledge that, while it responds to every test applied to it up to that moment, it may be modified by further discovery or absorbed into and covered by a theory of a more comprehensive character. The continuous advance of knowledge proves, however, that the foundations have been well and truly laid. "The scientific man seeks truth as a continually developing revelation, and he changes his outlook on the world according as it unfolds itself before his eyes. The priest teaches that in some remote period of the world God Himself revealed Truth once and for all time, and his profession is to guard it against all comers. I do not believe that the soul, any more than the mind, can stagnate. It must grow or decay. Christianity cannot be crystallised into a creed binding for all time, and least of all into a creed dating back to the century that preceded the relapse of Europe into intellectual barbarism. The world changes and has changed in the last hundred years out of all recognition . . . on account of the new revelations of science, though these have come about by a process the reverse

of supernatural. . . . They constitute an essential part of the whole truth, be our religious convictions what they may."

And there we must leave this interesting volume to the judgment of the many readers who will certainly be attracted by its contents.

W. A. T.

A Natural History of the Feelings.

The British Journal of Psychology: Monograph Supplements. No. vi. Pleasure—Unpleasure. An Experimental Investigation on the Feeling-Elements. By Dr. A. Wohlgemuth. Pp. vii+252. (Cambridge: At the University Press, 1919.) Price 14*s*. net.

WHAT the psychologists of the Würzburg school have so largely done for the thought processes, Dr. Wohlgemuth has here attempted for the feeling-elements of the mind. The investigation consists essentially of a lengthy series of introspections on the affective states produced by various sensory stimuli—given singly or in combination—carried out by four trained observers under strictly experimental conditions, the data thus obtained being submitted to a detailed consideration and analysis, and eventually summarised and expressed in seventy-seven rules. These rules, the author maintains, may be regarded as a first step towards the building up of a natural history of the feeling-elements—a task which should precede any systematic attempt at theorisation or at the application of the psychology of feeling to practical life.

A novelty in the presentation as regards work of this kind consists of the fact that the data from which the conclusions are drawn (*i.e.* the protocols of the observers) are recorded in full, occupying the largest portion of the book (137 closely printed pages), references in the margin indicating passages in the protocols from which the subsequently stated conclusions have been drawn. From the purely scientific point of view, this procedure has everything to recommend it. There exist no well-recognised and trustworthy methods of summarising introspective data, such as there are, for instance, in the case of purely quantitative results, and the presentation of the complete material enables the reader and critic to control at each step the author's conclusions, or to draw new and independent conclusions of his own, in a way that would not otherwise be possible. The opportunity of studying the observers' gradually increasing power of analysing and describing the fleeting affective contents of the mind should, moreover, be welcome to all who are interested in the possibilities of the modern method of exact introspection in psychology. On the other hand, the inclusion of the full data has increased by not a little the size (and doubtless also the cost) of the present work.

It is impossible to summarise adequately the wealth of conclusions arrived at from the study of the protocols. A very few only of the more salient points can be mentioned here. The observers find that "the feeling-elements are not attributes or functions of sensations or other cognitive processes, but a separate class of conscious processes. Although generally closely dependent upon the cognitive and conative processes to which they belong, they often show a certain independence and detachment." The feeling-elements possess two qualities only—pleasure and unpleasure, this result supporting the more common view as against the multi-dimensional theories advanced by Wundt and certain others. Unpleasure must be clearly distinguished from pain, which is not a feeling, but a sensation—"a sensation of a definite modality whose feeling tone is mostly unpleasant, but which may be neutral or sometimes even pleasant."

As regards the much-disputed question concerning the possibility of the co-existence in consciousness of distinct feeling-elements, some fairly strong evidence is brought in favour of such co-existence, the co-existing feelings being either of the same quality (*i.e.* both pleasant or unpleasant) or of different qualities (*i.e.* one pleasant, the other unpleasant). There are, however, important individual differences in the ease and frequency with which such co-existence can be observed.

A further disputed question—that of the localisability of the feelings—is also answered in the affirmative, the localisation of feelings being closely dependent on the observer's power of objectifying the feelings in question. In this connection it is interesting to observe that "the behaviour of feeling-elements is inverse to that of sensations in this way, that whilst sensations of the auditory and visual senses are more readily objectified than those of other senses, the feeling-elements when belonging to the former are less readily objectified and localised than when they belong to the latter."

An important difference between feeling and sensation was found in the fact that "there is nothing on the affective side of consciousness to correspond with the memory image on the cognitive side. The memory of a past feeling-element is merely knowledge—*i.e.* solely cognition. The affective experience attaching to an ekphored [*i.e.* recalled] cognitive experience is a new feeling-element, a new pleasure or a new unpleasure."

Another difficult point on which much light is thrown concerns the influence of attention upon feeling. At first individual differences were discovered which corresponded to the opposing views that have been held on this subject. It was found, however, that these differences resulted merely from a difference of attitude. "If a feeling-element is attended to as belonging to a cognitive content or as part of a situation or complex, it is intensified and becomes clearer; but if an attempt be made to focus the attention upon it to the exclusion of its cognitive concomitant, the feeling-element is destroyed." On the other hand, the feeling-element is also destroyed, or at least weakened, if attention is directed exclusively to the purely cognitive aspects of an experience.

Many of these results and of the others which we have no room to mention here have a practical as well as a theoretical interest, and the author anticipates that, as a result of the further study of the feelings, we shall be able to formulate canons in order to increase pleasure and reduce unpleasure, to evolve, in fact, a normative science of kalobiotics.

The book contains little or no theory, confining itself almost entirely to an elaborate statement and discussion of the experimental results. As such it makes, perhaps, a greater demand on the reader's powers of concentration and endurance than is the case with most of the works that have hitherto appeared on this subject. Nevertheless, it constitutes fairly certainly the most complete and satisfactory study of feeling from its own point of view, and is one of the most important existing scientific contributions to this aspect of psychology.

Radiological Diagnosis of Disease.

Radio-Diagnosis of Pleuro-Pulmonary Affections. By F. Barjon. Translated by Dr. James A. Honeij. Pp. xix + 183. (New Haven: Yale University Press; London: Humphrey Milford; Oxford University Press, 1918.) Price 10*s.* 6*d.* net.

THE author points out that the perfecting of the instruments used in radiological examinations has changed a process regarded at first as a mere curiosity into a useful scientific and practical method. Radiology has gradually extended its province in an extraordinary manner. It has entered the physiological and pathological study of all the important organs. In lesions of the lungs and pleura the radiologist can determine the topography of the trouble in a manner aptly called by Claude Bernard "a living autopsy." No other method of exploration demonstrates so clearly and simply the functions of the heart and lungs. It shows, without the cardiograph, the pulsations of the auricles and ventricles and the aorta. It estimates, without the spirometer, the respiratory value of the lungs, and shows the movements of the diaphragm, the intercostal spaces, and the displacement of the mediastinum in inspiration and expiration.

The author shows that the radiological method should not be used alone, but always in conjunction with other methods. "The radiologist must be a physician. The interpretation of X-ray results demands a very accurate knowledge of anatomy, physiology, and pathology." Conversely, it is well also for the physician to be, in a less degree, a radiologist.

The book contains a very full and complete account of the radiological appearances of the diseases of the lungs and pleura, with many valuable hints to help the observer from falling into errors of diagnosis. The subject of pulmonary tuberculosis is discussed in full detail. The perusal of this section leaves no room for doubt as to the extreme importance of the X-ray method in the diagnosis of this disease. Even in the early stages the exact position of the lesion is clearly shown, and its extent revealed. The progress of treatment, also, can be followed; in successful cases the gradual clearing of the affected portions of the lungs can be studied.

The last part of the book deals with penetrating wounds of the thorax by war projectiles. It shows how the nature of the projectile is to be recognised, how its exact situation within the thorax is to be localised, and how the radiologist may aid in deciding whether operative interference is advisable or urgently needed.

The book is printed in good type, and profusely illustrated by diagrams in the text and by half-tone reproductions of X-ray prints and negatives in plates printed on art paper.

The Manufacture of Artificial Fertilisers.

Mining and Manufacture of Fertilising Materials, and their Relation to Soils. By Strauss L. Lloyd. Pp. vi + 153. (New York: D. Van Nostrand Co.; London: Crosby Lockwood and Son, 1919.) Price 9*s.* net.

THERE is at present no good book in English on the manufacture of artificial fertilisers, but there is ample room for one. Mr. Lloyd does not quite supply the need. He evidently knows something about the mining and working of Florida phosphate rock and the making of superphosphate, but instead of giving a clear description of all this, illustrated by diagrams, he occupies

valuable space with an account of soils and soil analysis which the reader could far better obtain elsewhere. Yet there is scarcely a more vital industry at the present time than the manufacture of artificial fertilisers, nor is its importance likely to diminish.

The best chapters are the two on pebble phosphate and on hard-rock phosphate. The Florida phosphates are usually classified into four groups: hard rock, soft rock, land pebble, and river pebble, all of which occur in the Eocene and more recent formations. Of these the hard rock is the purest, containing phosphate equivalent to 80–85 per cent. of dicalcic phosphate; the land pebble contains somewhat less, while for the soft rock and river pebble the corresponding figures are about 55 to 68 per cent. The method of working is fairly well described. The remaining chapters, however, are not so good. More information might have been given about the mechanical dens and other contrivances used in the manufacture of superphosphate. Scarcely anything is said about the manufacture of mixed manures, although this is one of the largest branches of the business. The chapter on the fixation of atmospheric nitrogen is some years out of date; no mention is made of the Haber or the Ostwald process; the old view, now given up elsewhere, is still put forward, that cyanamide changes to "dicyanamide" (dicyanodiamide) and then to ammonia by bacterial action.

Should a second edition be called for, the author would be well advised to omit the chapters on soil and the science of manuring. It might also be wise to ask a chemist to read the proofs in view of his gibe about treatises on agricultural analysis with methods which the student "would have to unlearn if he entered a fertiliser factory, where he would have to analyse manures against chemists of some reputation." The reader would thus be spared some interesting specimens of chemistry which we hope are not typical of the new chemistry given in American fertiliser factories in place of the unlearned college work, such as:—

"The sodium chloride decomposed by the free phosphoric acid caused the bags to burst in transit, for there is no substance which rots bags like free chlorine and fluorine—two elements given off when nitrate and damp superphosphate are mixed."

E. J. RUSSELL.

Our Bookshelf.

Telephony without Wires. By Philip R. Coursey. Pp. xix+414. (London: The Wireless Press, Ltd., 1919.) Price 15s. net.

THIS book gives a fairly complete account of the practical development of radio-telephony. Accurate descriptions are given of very many types of apparatus. The book, therefore, is more useful for reference than for learning the principles of the art. Little space is devoted to theoretical considerations, but the author mentions some of the difficulties encountered, and indicates possible lines of advance. The bibliography is very complete, some 700 references being given to original papers on the subject.

From the commercial point of view, radio-telephony is not very attractive at present, as its applications are mainly confined to those cases where the ordinary telephone service cannot be used. It is possible by using very costly apparatus to telephone on land over thousands of miles. For instance, New York and San Francisco were put in telephonic communication in November, 1917, although the distance is 3400 miles. The experiment was successful, but it did not prove the commercial feasibility of such a long-distance service, as the value of the apparatus in use when talking was 400,000*l*.

Radio-telephony was very useful in the later months of the war, as communication was established by its use not only between aeroplanes and the earth, but also directly between aeroplanes. It has also proved useful in establishing communication between moving trains and the ordinary fixed telephone systems. During the last few years the rapid development of radio-telephony has been mainly due to the researches of the physicist and the mathematician. The problems it furnishes of absorbing interest, and it is rapidly widening our knowledge of the laws of Nature.

Scientific Method: Its Philosophy and its Practice. By F. W. Westaway. New edition. Pp. xxi+426. (London: Blackie and Son, Ltd., 1919.) Price 10s. 6d. net.

SIR J. J. THOMSON'S committee on the position of natural science in the educational system of Great Britain expressed agreement with the view that "some knowledge of the history and philosophy of science should form part of the intellectual equipment of every science teacher in a secondary school." There is no more enlightening and helpful volume from which to acquire such knowledge than this by Mr. Westaway. The implications of scientific reasoning, method, and practice are clearly presented, and the examples are both apt and instructive. Any science teacher, whether in university or school, who reads the book cannot fail to derive profit and interest from it.

In this second edition the chapter on "Philosophers and Some of their Problems" has been re-written, and is now a more precise statement of the specific claims of philosophy than was the chapter in the original issue. A new appendix, entitled "Retrospect and Reflections," surveys the function and influence of science and scientific method in national life, superseding one on "An American School Course in Chemistry." The index is missing in our copy of the book, though there was one in the first edition, but its absence is possibly due to a fault of the binders.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Organisation of Scientific Work.

THE relations between scientific inquiry and constituted authority, whether ecclesiastical or civil, have seldom been cordial or wholesome. Science was once a fearful dragon, to be destroyed or confined. With the discovery that the beast had powers from which profit could be made by cunning masters, it was found more expedient to tempt him into harness. Our former state was probably the better, or at least the safer, and most of us will agree with Prof. Soddy that the scheme devised by the Indian Industrial Commission is simply an offer of servitude undisguised. While there is time, those with whom the decision rests should be told very plainly that the adoption of such rules of service as those quoted in the leading article in NATURE of February 19 must mean the alienation of all sincere and genuine investigators.

Research, like art, literature, and all the higher products of human thought, grows only in an atmosphere of freedom. The progress of knowledge follows no prescribed lines, and by attempting such prescription the head of a Service would merely kill the spontaneity and enterprise of his workers. No one fit to be entrusted with research worthy the name would undertake it knowing that his results might be burked or withheld from publication at the whim his superior in the Service. Such conditions may appropriate to certain forms of technical or industrial invention, where the sole purpose is to get ahead of a trade rival, but we can scarcely imagine that the vast and manifold undertakings promoted by the scientific services of the Indian Government are to be conducted in that spirit.

W. BATESON.

The Manor House, Merton, S.W.19.

I HOPE you will allow me to express through the medium of NATURE my concern at the proposal referred to in the leading article in the issue of February 19 to centralise in an Imperial Department the various scientific services in India—a policy which I believe to be likely to prove detrimental to good work. I was a member of the Indian Forest Department during the years 1871–99, so that my Indian experience is not very recent, but I have kept myself informed of what was going on. Since I left India research institutes have been established in different provinces with officers attached to them required to devote themselves to the study of scientific questions. In my opinion, it is of the utmost importance that these officers should have as free a hand as possible, and be allowed to work in their own way on the subjects which they know themselves most competent to study. If they are called upon to work under a centralised Department, and perhaps to turn from branches of study which they thoroughly understand to others in which they may have to begin by reading up, much of their time will be wasted and the results poor.

A centralised Department, to most people of Indian experience, means many reports and returns and constant correspondence, and I believe the result of such an innovation will be that some hours at the beginning of each day will have to be spent on what may be called "clerical duties." If a scientific worker is to do his best, he must be able to spend *all* his time on his researches, and not be obliged to waste much of the day on clerical duties, only beginning his real work when tired and unable to do his best.

Centralisation will also mean, in my opinion, the spending of much money in keeping up clerical staffs, which, as most Indian officers will admit, have a wonderful tendency to increase. It will be much better that the recommendations of the last paragraph but one of your leading article should be followed and the money spent in giving financial assistance to the universities and research institutes instead. The paragraph to which I refer puts the arguments for the continuance of the present system and its better development excellently in a few words, and I trust it may have the effect on the administrative authorities that I feel sure it must have had on the scientific men who have read it.

J. S. GAMBLE.

Highfield, East Liss, Hants, February 25.

I HAVE not yet had time to study the Report of the Indian Industrial Commission, and may, therefore, be ignorant of some of the arguments for centralisation, but I am certainly in general agreement with the views expressed in the leading article in NATURE of February 19, and by Prof. Soddy and Dr. Rendle in the issue for February 26, regarding the dangers of that method of research organisation. Investigations under centralised bureaucratic control must almost always be concerned solely with questions capable of receiving easy and immediate replies, for the obvious reason that directors and committees can rarely be persuaded to authorise attacks upon difficult or distant objectives, regarding which, perhaps, no replies at all may be forthcoming. Now the most important discoveries have generally been made precisely by such attacks, and investigation is a lottery in which the greatest prize often falls to him who takes the greatest risks. Directors and committees do not like risks, and, consequently, seldom make discoveries. I should like to know, for instance, how any "Indian Scientific Service" would have attacked the malaria problem, which I commenced to assault (in a very foolhardy manner!) in 1890. I am sure it would have refused to authorise my attempts, and even to publish my first results. On the other hand, it would have wasted, with ripe bureaucratic prudence, thousands of pounds in looking for Plasmodia in marshes, or in trying to correlate various species of mosquitoes with local outbreaks of the disease, and I am sure it would have achieved nothing at all up to the present day.

We forget that, like really valuable art and invention, scientific discovery is almost always due mainly to the individual. One might as well try to organise an Institute for the Writing of Poetry as institutions for making great discoveries or inventions. Like art, discovery is creative. It depends much more on the brain than on the hand, even in work requiring the most careful manipulative skill. Scientific services will not be able to pick up "discoverers" on every bush. All they can do is to organise hand-work, for which they may be useful. But if the Government of India wishes to obtain great results for its expenditure it must *buy genius*. Now genius may be defined as the quality which achieves success, and the only way to buy it is to reward success—as suggested by the Committee on Awards in NATURE of January 8. What we all fear is that the Government of India will be tempted to spend much larger sums of money in buying, not genius, but its opposite.

At the same time certain researches, even of a petty kind, will require subsidies, and the Government

ought also to possess expert advisers in many branches of science. Some kind of scientific service will therefore be needed, but this should not be allowed to engross the whole field; and the best results are sure to be obtained in the future, as they have been in the past, by untrammelled men of capacity working as they please. RONALD ROSS.

IN discussing the best ways of fostering research work it is important to remember that the word "research" is used in two widely distinct senses: it may stand either for the careful collection of observations, or for the deduction of the principles expressing the relationship between one set of phenomena and another. The difference between them is like that between the discovery of a new country and the careful mapping of one known in a general way but not in full detail.

It would be unfair to set either of these kinds of research above the other; each is indispensable to the other. Experience shows, however, that the power to collect careful observations can be imparted to a large number of men and women, while the power to utilise the material and deduce from it anything more than the comparatively obvious is rare and cannot be imparted. Further, this ability is not equally divided as between different classes of men or as between men and women.

The recognition of the necessity for each kind of ability is essential to the proper conduct of a research institution, and one of the great difficulties is to find deducers of new ideas and to ensure that they shall work harmoniously with the equally necessary, but less rare, collectors of observations. The difference between the two groups of workers is fundamental and far-reaching, manifesting itself even in trivial daily actions. One difference is particularly important for the present discussion: the first group greatly resent immediate direction; the second do not, provided they see advantages therein. In all research institutions of any size the chief problem is to keep both groups of workers as nearly abreast as possible. Deductions made in advance of facts are often wrong and sometimes harmful. Facts and observations accumulated without any illuminating hypothesis or general principle are rather dreary and soon forgotten. It is one of the tragedies of a life devoted to science that so often the fruit falls stillborn and is entombed in some journal, never again to see the light. We have all known such workers:

> And, as year after year
> Fresh products of their barren labour fall
> From their tired hands, and rest
> Never yet comes more near,
> Gloom settles slowly down over their breast.

The only way of avoiding the tragedy and its accompanying waste is to ensure that both groups of workers keep together.

It is not only between these two groups, however, that co-operation is necessary; under modern conditions there must also be close relationship between the workers in different subjects. Science is becoming increasingly specialised; no one man now knows much of any subject except his own. For the investigation of phenomena such as those of agriculture, which lie outside the present arbitrary divisions of science, recourse must be had to team-work; a body of young workers whose minds are still elastic must be interested in the problem and induced to work together for its solution.

Experience shows that successful co-operation is achieved only when a deliberate attempt is made to secure optimum conditions for each individual worker.

How can a State system be adapted to fit these various necessities? For financial reasons complete elasticity is impossible; Treasuries must know their liabilities. In any Civil Service system promotion is almost inevitably by seniority. Individual action and thought would be intolerable; everything must go through a chief, while anything repugnant to him must be suppressed. In all these directions the State system is absolutely incompatible with living research, although it might be consistent with much careful accumulation of facts, with survey work, and with the establishment of some central collecting institute. For these reasons I cannot believe that the intensely centralised system proposed for India could succeed. One man may organise work in one institution where he is accessible to the staff morning, noon, and night; but he would indeed need to be a superman of most exalted degree if he aspired to direct the research work of a country.

The system devised by the English Ministry of Agriculture is, in my view, much better. It possesses some degree of financial elasticity. While it contains the inevitable regulation about promotion by seniority, this is qualified by clauses under which the best man available can, nevertheless, be appointed to fill a vacant post. There is no attempt to govern from Whitehall; no general director, deputy director, or other official to run the research workers, but only occasional friendly gatherings of the chief officers to discuss common problems. Could not some such system be tried in India? E. J. RUSSELL.

Rothamsted Experimental Station, Harpenden.

THE question of reorganising and developing scientific work in India discussed in the leading article in NATURE of February 19 is of the utmost importance to all concerned with the welfare and scientific reputation of the Empire. Now that there is a prospect of recognition by the Government of India and the Secretary of State of the necessity for increased expenditure on scientific investigation, it is essential that the new era should be inaugurated under the most favourable conditions. Two policies are apparently under consideration, which may be referred to respectively as centralisation and decentralisation; these are clearly defined in the article of February 19. The advantage of organising research within certain limits is generally admitted; facilities should be afforded for supplying information, for suggesting problems, and for the co-ordination of the activities of individuals or institutions, but it would seem that the policy of centralisation advocated by the Indian Industrial Commission, presided over by Sir Thomas Holland and "favoured by a number of administrators," is much more than this. It is, in short, a proposal to bring scientific investigation into line with routine official work—a procedure which, one learns with surprise, has the support of several scientific witnesses examined by the Commission. If there is one thing vital for the successful prosecution of scientific research of the best type and for the encouragement of the full development of a researcher's capacity, it is freedom of action.

It is safe to predict that very few men possessing what may be called the research temperament would consent to submit to a bondage that would be not only irksome and irritating, but also fatal to individual initiative and enthusiasm. If adequate remuneration is offered and reasonable laboratory facilities are provided, good men will be easily secured. Given the right sort of men, I venture to think that the only rational course is to trust them to work out in

their own way, with such advice or assistance as may be asked for, the problems entrusted to them.

The appointment of a head for each department of science with the powers of a dictator would be the surest means of encouraging mediocrity, and of warning off just that type of original thinker and independent investigator whose services would be of inestimable value to the State. It may be contended that any State scheme, whether concerned with routine duties or original work, must be under some central direction, but there is no reason why the direction should be of such a kind as would be tantamount to asking every researcher to place himself, body and soul, under a dictator.

The Constitution of the Elements.

IN continuation of my letter on the above subject in NATURE of December 18, 1919, several more elements have been subjected to analysis, yielding interesting "mass-spectra."

Argon (atomic weight 39·88 Ramsay, 39·91 Leduc) gives a very strong line exactly at 40, with double charge at 20 and triple charge at $13\frac{1}{3}$. The last line, being closely bracketed by known reference lines at 13 and 14, provides very trustworthy values. At first this was thought to be its only constituent, but further photographs showed an associated faint line at 36. This has not yet been proved an element by double and triple charges, as the probable presence of OH, and the certain presence of C prevent this, but other lines of reasoning make it extremely probable that this is a true isotope, the presence of which to the extent of 3 per cent. is enough to account for the fractional atomic weight quoted.

Helium was compared with O++ (8) by a special system of bracketing, and directly with C++ (6) by extrapolation. Both methods give its mass as 4, with an accuracy of 2 or 3 parts in 1000.

By the same methods H_1, H_2, and H_3 all give consistent results for the mass of the hydrogen atom as 1·008 within experimental error, agreeing with the value given by chemical analysis, and, incidentally, confirming the nature of H_3 beyond doubt. *These three lines are the only ones diverging from the whole number rule to a definite and measurable extent.*

Nitrogen is apparently a "pure" element, its doubly charged atom being 7 exactly.

Krypton (atomic weight 82·92) has no fewer than six constituents: 78, 80, 82, 83, 84, and 86. The last five are strong lines most beautifully confirmed by double- and triple-charged clusters, which can be compared with great accuracy against A (40) and CO (28). These reference lines obliterate one of each group, but not the same one. The 78 line has not yet been confirmed in this way owing to its faintness, but there is no reason to doubt its elemental nature. Krypton is the first element giving unmistakable isotopes differing by one unit only.

The partial pressure of xenon (atomic weight 130·2) in the gas used was only sufficient to show its singly charged lines clearly. These appear to follow the whole number rule, and rough provisional values for the five made out may be taken as 128, 130, 131, 133, and 135.

Further examination of the multiply charged mercury clusters indicate the probability of a strong line at 202, a weak component at 204, and a strong band including 197 and 200, unresolvable up to the present.

Deflection of Light during a Solar Eclipse.

PROF. ANDERSON has suggested in NATURE that the apparent displacement of stars observed during the solar eclipse may be ascribed to an unusual form of refraction in the terrestrial atmosphere. The discussion which has followed shows some lack of agreement as to the importance of such a refraction effect. I wish to suggest that it might, perhaps, be possible to form an estimate of the magnitude of this effect by making measurements of the apparent diameter of the moon during the eclipse. Star photographs would seem to be somewhat unsuitable, although one diameter of the moon may leave a clear enough trace on the plates (a diameter at right angles to the apparent motion of the moon relative to the stars). It should be possible, however, to obtain sharp silhouette images of the moon on plates devoted to this particular purpose; perhaps such photographs are already available. The nature of the clockwork drive needed is dependent on the necessary exposure, and need not be discussed.

J. A. ORANGE.

MR. ORANGE's point is, of course, that we should use the one object in the field of which the light has not been through the sun's gravitational field in order to get rid of the Einstein disturbance; also of the suggested refraction by gases near the sun. I have talked the matter over with Mr. C. Davidson, who agrees with me that nothing is to be done with existing photographs in this direction—the exposures were too long, and the moon's limb too ill-defined; but it is possible that in future eclipses short exposures, given specially for the purpose, might yield something of interest. The chief difficulty is that we do not know the moon's dark photographic diameter. It cannot be assumed equal to the bright photographic diameter, for irradiation (and other similar actions) go in the reverse direction.

Perimeter of an Ellipse.

THE following approximate formula for finding the perimeter of a fairly flat ellipse may be found practically useful. Suppose $a=1$, then the length of a quadrant of the ellipse is nearly

$$1+0{\cdot}66b^2,$$

where a is the major, and b the minor, axis. The formula works best from about $b=0{\cdot}2$ to $b=0{\cdot}5$, after which the formula of Boussinesq is more accurate, viz.

$$\frac{\pi}{4}\left\{\frac{3}{2}(1+b)-\sqrt{b}\right\}.$$

But the formula I give is for practical purposes quite satisfactory up to $b=0{\cdot}6$, the relative error never being large. It does not work if the ellipse is nearly circular. Boussinesq's formula is of no use if the ellipse is flat.

Other more accurate formulæ could be given, but the above has the advantage that it can be calculated very rapidly, and, within the range mentioned, I doubt if higher accuracy is ever required in practice.

Scientific Research and the Glass Industry in the United States.

By DR. M. W. TRAVERS, F.R.S.

THE great American glass works engineer, Mr. Owens, referring to the fact that he had been refused admission to an English glass works, once observed to a friend of mine, "If a man refuses to admit me to his plant I generally reckon that he is ashamed of it." I had often wondered whether Mr. Owens's countrymen really practised the policy which he preached, and last autumn the opportunity offered of putting it to the test. During a seven weeks' tour through the States I paid almost daily visits to glass plants, with no other introduction than the information conveyed by my private visiting card, and only once was my visit restricted to the office. Generally I was shown the whole plant, and all my questions were frankly answered; sometimes I was even permitted to make a second round of the works on my own account. In the research laboratories of both private companies and great industrial corporations I was made doubly welcome. I can only express a sense of obligation, which I can never repay.

It was very frequently that I heard statements made to the effect that the application of science to industry in America was only in its infancy. It is a fact that American industry is absorbing the whole output of the universities, and also drawing men from this country. America has found the application of science to industry to be a proposition which appears to be a sound one, and, in conformity with American industrial policy, means to give science a fair trial. If men of science prove their value from the commercial point of view, they will rank equally with men of business capacity, who are able to dictate the terms of their service to industry.

It must be remembered that the American glass industry is relatively small, and even in Pittsburgh, where the glass factories are most numerous, it is entirely overshadowed by the steel industry. However, so far as scientific research goes, the industry is in a remarkably favourable position. The Geophysical Laboratory at Washington, D.C., which I visited, is primarily an institution for the investigation of scientific problems connected with glasses, of which the earth itself so largely consists, and the Bureau of Standards has devoted a considerable amount of attention to the subject. In April, 1917, soon after America joined in the war, American industry had to face a demand for an immense amount of optical glass. The work done by the staff of the Geophysical Laboratory is told in a few words in the director's report for 1918: "Suffice it to say that with a staff of twenty scientifically trained men, all trained in the handling of silicate solutions at temperatures required for the making of glass, and familiar with the control of the most important factors in the problem, it proved practicable to make rapid progress." After two months the output had doubled, and rejections by Government inspectors had become very rare. A few months later "the output had reached a magnitude such that an adequate supply of suitable glass was assured for national needs, and . . . many refinements were being effected to bring the quality of the glass to a higher level."

To achieve these results, the staff of the Geophysical Laboratory did not remain in Washington and issue advice to manufacturers, but actually took over the scientific control of the plants, some of which were built after America's entry into the war, and in such positions I still found some of them when I was in America. The Bureau of Standards also established a small manufacturing plant in Pittsburgh, and here some very important work on glass pots for optical glass manufacture was carried out by Dr. Bleiniger. Accounts of much of this work have been published in the *American Journal of Science* and the Journal of the American Ceramic Society, and the work is described as being carried out "at the Geophysical Laboratory and at the plants of the Bausch and Lomb Optical Co., Spencer Lens Co., and Pittsburgh Plate Glass Co., under the authority of the War Industries Board." Anyone who is interested may learn exactly what was accomplished and what the position is at the moment, and may visit such of the plants as are in operation. Can anyone say what really has been accomplished in connection with optical glass in this country, what remains to be done in order to establish the industry, and what organisation exists for doing it?

The Bureau of Standards is, of course, an official institution; the Geophysical Laboratory is maintained by the Carnegie Institution, and is not under the control of Government. I do not know how far the experimental work in connection with optical glass was subsidised by the Federal Government, but during the war very substantial funds for research work were at the disposal of the National Research Council, which was organised, at the request of the President, by the National Academy of Sciences, and money from this source was available for such purposes. It must be noted that wherever an appointment had to be made in any matter of a scientific character, even in the case of officials, it was made on the recommendation of the men of science. In this we find an essential difference between American and British practice.

The development of scientific glassware, other than optical glass, was left to individual effort, and was solved with equal success by several firms. The Corning Glass Works, at Corning, N.Y., succeeded, however, in producing a very remarkable glass, which is called "Pyrex" glass, from which are manufactured both chemical hollow-ware and the so-called oven-ware. This glass has so low a coefficient of expansion and so high a tenacity that one can take extraordinary liberties with it, and it is much more highly resistant to changes of temperature than any glass previously produced. The

production of this glass is a very remarkable achievement.

"Pyrex" glass and the Empire bulb-blowing machine were only two of the many interesting developments which I was shown at Corning. When I was there, Dr. A. L. Day, who has long been connected with the works, was acting as vice-president of the company; and Dr. E. C. Sullivan and Dr. W. C. Taylor, assisted by a considerable scientific staff, were in charge of the technical side of the work. Dr. Taylor told me that they had been carrying out a systematic survey of possible combinations in glasses, and that as each glass was made experimentally its properties were investigated and recorded. In the Steuben Works, which are under the same management, and only a few hundred yards distant, Dr. J. C. Hochstetter was collaborating with Mr. F. C. Carder in the investigation of problems relating to coloured glasses.

Scientific glassware was also being manufactured at the H. C. Fry Glass Works, where I spent a day with Dr. Scholes and his staff, and at the Macbeth Evans Glass Co.'s plant, also near Pittsburgh, Pa., over which I was shown by Dr. Macbeth and Prof. Hower, who is consultant to the firm. I found quite a numerous scientific staff working in excellent laboratories.

In the bottle-making branch of the industry the engineer predominates. I believe that the first bottle machine was English, and one would like to know why it is that the development of bottle machinery has been practically wholly American. The Owens machine, the Hartford-Fairmont flow feed, the Westlake machine, and the Empire machine are purely American, and they are American because Americans understand the value of science organised in the service of industry, and are willing to give good brains a fair chance and to back them with good money. Developments in this direction are entirely a matter of private enterprise, in which consumers as well as manufacturers are often financially interested.

To no branch of the glass industry has science been of greater service than to that of the electric lamp industry. I was able to spend two days in the research laboratories attached to the great plant of the General Electric Co. at Schenectady, in company with Drs. Whitney, Langmuir, Coolidge, and Hull, whose names are as well known in Europe as in America. The staff of the laboratory is said to number more than 150 members, and the work carried on is in some cases purely scientific, and in others highly technical, processes being actually worked in the laboratory until the demand for the goods or material produced justifies the erection of separate factories. While I was at Cleveland, Ohio, Dr. W. M. Clark, the chief chemist of the National Lamp Association, was good enough to show me over the whole plant of his firm. Here a physical laboratory dedicated to investigations connected with illumination, but only indirectly with artificial lighting, has been established in recognition of the services of science to the industry.

In several of the universities research is being carried out in connection with glass, and I had the good fortune to meet both Prof. Washburn, of Illinois University, and Prof. Silverman, of Pittsburgh University, and to discuss with them their work on the chemistry and physics of glass.

A short article permits me to deal only with isolated incidents in my tour, but the impression which I brought away with me and wish to convey to others is that there are a great many men of high scientific ability engaged in the American glass industry, which has learned, as the German glass industry learned, to our undoing, that industrial progress implies the co-operation of science and industry. American industry is not securing the co-operation of science for sentimental reasons, but with a view to competition with us in the markets of the world. To this movement science, through the National Research Council, organised by the National Academy of Sciences, in co-operation with the national scientific and technical societies of the United States, is giving its heartiest support.

The Circulating Blood in Relation to Wound-Shock.[1]

By PROF. W. M. BAYLISS, F.R.S.

THE system of vessels in which the blood is contained must be conceived of as a *closed* system. But the walls are distensible and elastic; they can therefore stretch and collapse to accommodate varying amounts of liquid. This is possible, however, only to a limited extent. Although the veins have thinner walls than the arteries, and appear to be less supported by surrounding structures than are the capillaries, it is remarkable that they oppose a greater resistance to a bursting pressure than do the arteries. Veins, moreover, have a muscular coat which is in a more or less contracted state during life. Hence the introduction of more fluid into the system must encounter a certain resistance and raise the internal pressure, unless the muscular coat actively relaxes to accommodate the fluid introduced.

This closed system contains, under normal conditions, about four litres of blood in man. It consists, as is generally known, of the heart, of branching tubes (arteries), leading from the heart to the tissues, where they break up into a network of much finer tubes, the capillaries, which unite again to form the veins, and so lead the blood back to the heart. Consider the distribution of the blood at the time when the heart is at rest.

[1] Discourse on "The Volume of the Blood and its Significance," delivered at the Royal Institution on Friday, February 13.

The amount present in each part, including the heart itself, is obviously in proportion to the capacity of each part.

The heart, however, works as a pump. The way in which the blood is circulated was first clearly propounded by Harvey in 1616, although Leonardo da Vinci came very near to the discovery more than a century before. Harvey saw the blood sent out from the heart, propelled to the tissues in the arteries, and returned to the heart by the veins. The course of the blood from one to the other through the minute capillaries could not be seen until the invention of the microscope by Leeuwenhoek, who made use of it in 1686 to observe the blood traversing the capillaries in the tail of the tadpole.

The heart, then, when it contracts, drives out the blood which is contained in its cavities, or nearly the whole of it. This same quantity must be returned by the veins, otherwise the blood would soon all be accumulated in the peripheral parts of the body. Further, the heart is capable of driving out the more blood the greater the quantity it contains when contraction begins. This is what has been called by Starling the "law of the heart." It depends on the fact that muscular fibres contract the more powerfully the greater the length to which they are stretched to begin with—within limits, of course.

We see, therefore, that the amount of blood driven through the organs of the body in a given time depends on the amount present in the heart at rest. Since this is a definite fraction of the whole blood, the irrigation, as we may call it, of the body is in proportion to the total quantity of blood available. The importance of sufficient irrigation is obvious. The blood conveys to the active cells the materials required for their work, and of these the most necessary is oxygen. If the supply is too meagre, the first few cells with which the blood meets exhaust it, and those beyond suffer from deprivation. Waste products are removed at the same time.

Although the part played by the volume of the circulating blood in relation to the capacity of the vascular system was realised by Carl Ludwig and his school, who made many experimental investigations on the subject, the matter came especially into prominence in connection with the explanation and treatment of the state known previously as "surgical shock," but which occurred with alarming frequency in men wounded in the late war. The name "wound-shock" is a more comprehensive name, although the use of the word "shock" is liable to give a misleading impression as to the rapidity of its onset, and to cause confusion with "shell-shock," another unsatisfactory name, but used to designate an affection of the nervous system of quite a different nature from that brought about by the wounds themselves. Wound-shock is not easily defined in such terms as to distinguish it clearly from other similar states, such as that due to loss of blood, but it may be said to be one of general collapse, ending in death if not combated in some way. It does not come on immediately after injury, but in the course of some two or three hours. It shows itself by pallor, coldness, sweating, vomiting, thirst, low blood-pressure, and the other symptoms which were early recognised as indicating a defective circulation.

But what is the actual cause of this collapse of the circulatory mechanism? It was soon realised, by those who examined cases of wound-shock, that it was not due to any failure of the heart itself, nor was the central nervous system involved, except indirectly in the later stages. On the other hand, much difficulty was found in distinguishing between this state, even when attended by very little loss of blood, and that resulting from great loss of blood unaccompanied by serious injury. The latter is obviously the result of the defective volume of blood and its consequences, since blood is known to have left the body. But why do the former cases also appear to be suffering from the same condition, when scarcely any blood has actually been lost?

In the endeavour to find an explanation for this, we may call to mind the circumstance that blood may be effectively removed from circulation by being pooled away in some part or other of the vascular system, as, for example, by a great dilatation of this part. The amount which is available for propulsion by the heart to serve for continuous irrigation of the tissues is reduced as much as it would be if the blood held in the pool were actually lost to the outside. Such changes in the capacity of the peripheral blood-vessels play a large part in the regulation of the blood-pressure and the supply of blood to various organs. We may inquire whether anything of this kind happens after severe injuries.

The first step taken in the course of this inquiry was the discovery that some poisonous substance is produced in injured tissues. This, passing into the blood, is carried to all parts of the body. Sir Cuthbert Wallace, some years ago, had noticed that operations in which the cutting of large masses of tissue was involved were especially liable to be followed by shock. Quénu and others, during the war, were struck by the rapid benefit frequently ensuing from removal of the injured parts or even when they are tied off from connection with the rest of the blood-vessels, if such is possible. Cannon and myself found that we could produce the state of wound-shock in anæsthetised animals in the laboratory, and that it was due to a chemical agent, not to any effect on nerves. This being so, we see that we can replace the name of "wound-shock" by the more descriptive one of "traumatic toxæmia."

But can we form any conclusion as to the chemical nature of this toxic substance or as to the way in which it acts? It is evidently produced too quickly to be a result of bacterial infection, and, indeed, McNee was able to exclude this possibility quite definitely. Dale and Laidlaw, however, showed that there is a compound of known chemical structure, called "histamine,"

and produced without difficulty from a constituent of the nitrogenous cell structures, which is able to produce a state of the circulation like that present in wound-shock. It was found that the effect was not due to a dilatation of the arterial part of the system, as was known to be the case in the fall of blood-pressure brought about by vaso-motor reflexes. Here the similarity to traumatic toxæmia showed itself again, because it was known that arterial dilatation was not present in this state. Next, Dale and Richards, by a number of ingenious experiments, were able to localise the effect in the capillaries, which became widely dilated and thus capable of taking up the greater part of the blood in the body, leaving the heart nearly empty, with too meagre a supply to carry on the circulation with any degree of efficacy. It is to be admitted that we have not yet definite proof that it is histamine itself which is responsible for the toxæmia of injury. But that the agent is something which acts in the same way is made clear by the observations that have been made on wounded men. The determinations of the volume of the blood in circulation, made by N. M. Keith, may be especially mentioned. Keith showed that, in severe cases, it may be reduced to little more than half the normal amount, although scarcely any has actually been lost by hæmorrhage. The method used was that of introducing into a vein a known quantity of an innocuous dye which does not pass through the walls of the blood-vessels, and, after a short interval, taking a sample of the blood and finding how much the dye has been diluted.

If the toxæmia is severe, a second property of the poison shows itself. This is an effect on walls of the capillaries such that they allow liquid part of the blood to escape by filtration. In this way the volume of the blood is still further reduced.

The treatment, in principle, is obvious. Restore the blood-volume. It would appear that when blood has been lost it ought to be replaced by blood. The case of traumatic toxæmia is not so clear at once, because blood has not been actually lost, and it should be possible to keep up an effective circulation by some other liquid until the poison is got rid of and the pooled blood returned to circulation. In fact, as experience increased, it was realised that the important matter is to maintain the volume in circulation, whether by blood or other solution. An innocuous fluid seemed to serve practically as well as blood, and had the advantage of being always at hand and in as large a quantity as required.

As to the properties of such a solution, it was soon found that a simple saline solution is very rapidly lost from the circulation and is useless. It is necessary to add to it some colloid with an osmotic pressure, such as gelatin or gum acacia. The colloid does not pass through the walls of the blood-vessels, and its osmotic pressure causes an attraction of water to balance that lost by filtration. Thus, although the slow circulation incidental to a small volume of blood is inadequate, this very quantity, if diluted to normal volume, is able to serve effectively. Comparing the oxygen carried by the red corpuscles to railway passengers, it will be realised that if we have a limited number of trains, we can carry more passengers in a given time if the velocity of the trains is increased. Animal experiments made by Gasser showed that this is actually the case with the blood. After a loss of blood the injection of gum-saline might even raise the supply of blood-corpuscles to a level beyond what it was before the hæmorrhage.

The general conclusion is that the volume of the liquid in circulation must be kept up to its normal value, whatever this liquid may be. Of course, the number of red corpuscles cannot be allowed to fall below some particular value, and it has been found that about one-quarter of the normal quantity is the lowest compatible with life. If they fall below this, moreover, there is no production of new corpuscles.

In the later stages of the war gum-saline was largely used in the British, American, and French Armies, and is reported to have saved many lives. Unfortunately, if too long a time is allowed to elapse before treatment, nothing avails, not even transfusion of blood. Hence the importance of the early use of intravenous injection, and also of removal of the injured tissue by operation. As the war progressed, these procedures were, therefore, pushed more and more forward to the battle area, and with more and more favourable results.

Characteristics of Pigments in Early Pencil Writing.

By C. AINSWORTH MITCHELL.

PENCIL pigments may be classified in the following groups: (1) Metallic lead or alloys of lead; (2) graphite cut from the block; (3) early composite pigments containing graphite, sulphur, resins, etc., but no clay; (4) graphite powder compressed into blocks; and (5) composite pigments containing graphite with clay and other ingredients. These pigments usually show distinctive microscopic characteristics in the marks which they produce.

When examined under the microscope with a magnification of about twenty diameters and the light at right angles, ordinary lead shows, in its vertical markings on paper, a series of irregularly distributed patches, uniformly and brilliantly lit up, and marked with regular vertical striations which have the appearance of ridges. In the case of Borrowdale graphite (Fig. 1) the vertical lines show relatively few brilliant straight striations (due to siliceous impurities), and when these occur in the

heavier strokes they are disjointed and irregular. The fibres of the paper may be brilliantly lit up by particles of adhering graphite which reflect the light, especially in those places showing a metallic lustre to the naked eye. Less pure forms of graphite show more numerous striations, but these are always more or less disjointed and irregular, and quite distinct from the fine striations in modern pencil markings.

The composite pigments (containing sulphur) in early specimens of pencils in South Kensington Museum, which Mr. T. H. Court kindly placed at my disposal, show a faint greyish pigment, with occasional striations, whilst Brockedon's graphite (1843) (Fig. 2) and other kinds of compressed graphite produce lines which show a rich black pigment with silvery dashes and lines distributed fairly uniformly all over the field.

Modern pencil compositions, mainly of graphite, clay, and wax, all have a similar microscopic appearance in the vertical lines made by them on paper, which is quite different from the markings of the old pencils of natural graphite, and in most cases from those made from the old compressed graphite powder. In the modern pigments the fine siliceous particles, derived from the clay and impurities in the graphite, are evenly distributed, and appear in the pigment on paper as fine beaded striations, which are uniform and parallel throughout the line (Fig. 3). Chemical methods of distinguishing between these pigments have been described by the present writer (*J. Soc. Chem. Ind.*, 1919, xxxviii., 383T).

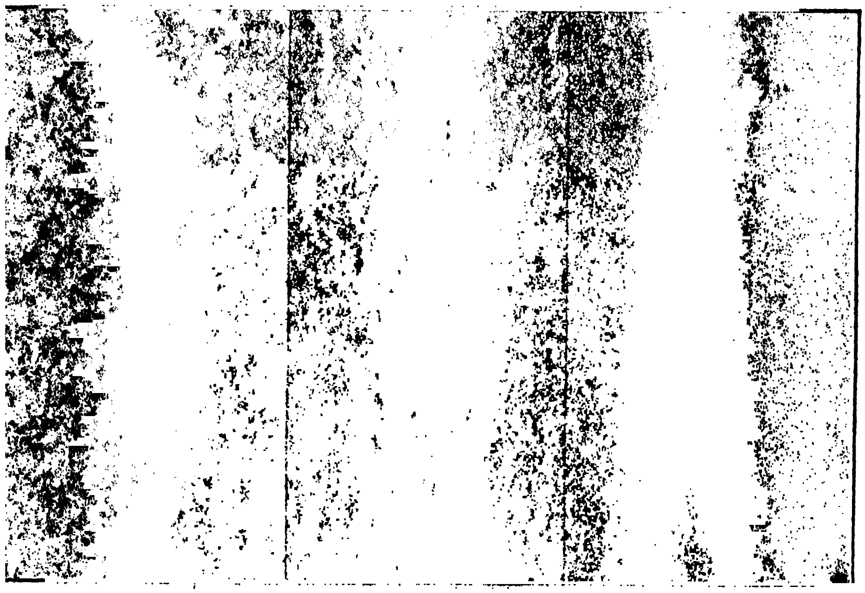

FIG. 1.—Typical early graphite marking, 1831. × 20.

FIG. 2.—Brockedon's compressed graphite, 1843. (Mark made by specimen in Geological Museum). × 20.

FIG. 3.—Typical modern composite pencil. × 20.

Some particulars of early pencil markings are given in a curious book by C. T. Schönemann (*Versuch eines Systems der Diplomatik*, Leipzig, 1818, 2 vols.) upon the codices preserved in the libraries in Germany. In vol. ii. (p. 108) it is asserted that lines in blacklead (*Reisblei*) had been drawn on the "Codex Berengarii Turonensis" of the eleventh or twelfth century, which was in the Wolfenbüttel library. The "Codex Guidonis Aretini de Musica" (eleventh or twelfth century) in the Göttingen library contained vertical and horizontal lines showing traces of blacklead (p. 112), whilst the "Codex Theophili" (twelfth century) in the Wolfenbüttel library showed very fine vertical lines in blacklead.

Now, as graphite was not known until about 1560, it is obvious that Schönemann mistook the markings in ordinary metallic lead for graphite. Through the kindness of Mr. J. P. Gilson, of the MSS. department, I have been able to examine specimens of early pencil marks in the writing and drawings in manuscripts in the British Museum. The earliest example was a drawing in the Stowe MSS., "Arms of Ancient Nobilitie" (705), of the early seventeenth century. The particles composing the lines of this drawing all reflected the light brilliantly, but were much smaller, and lacked the striations which are characteristic of metallic lead. On the other hand, the lines had not the appearance of any form of graphite, the particles being disjointed and not showing any connecting interrupted striations, as are often to be seen in lines of graphite having a metallic lustre. It is therefore probable that this drawing was done with a metallic pencil in which lead did not predominate.

A later MS. (1691) (Add. 22,550) includes drawings in which the lines show the large isolated particles with the vertical striations characteristic of metallic lead. In another Stowe MS., 686 (*circ.* 1630), the lines in the drawings have the appearance of ordinary graphite. The pencil markings in two note-books of Sir Thomas Cotton (Harley, 6018, about 1630–40) and Cotton Appendix, xlv. (1640–44), have all the characteristics of graphite.

The writing in Lord Hardwicke's "Notes on Briefs" (1718) is undoubtedly in graphite, but a drawing by Vertue (Add. MS. 2111) (1741) has the appearance of metallic pigment. A note-book of Hogarth (Egerton MS. 3011) (prior to 1753) contains heavy pencil writing, the pigment of which is a particularly rich graphite.

The pencil outline of a drawing on the top of ink in another of Hogarth's note-books is also in typical graphite. The lines in the drawings of a later volume of Stowe MSS. (993), about 1747, show fine interrupted striæ, such as are frequently noticeable in the marks made by pure graphite. In "Heraldic Collections" (Stowe MS. 661) of 1763–64 the pigment in the drawings of the coats-of-arms is also in graphite, and shows the fibres of the paper lit up by adherent particles. An interesting example of graphite markings is to be seen in a letter from Prof. Herrmann (1780) from Strasbourg (Add. MS. 22,935, fol. 140b). This contains a pencil drawing of a fish, in which the pigment has formed branching striations along the lines of the paper fibres.

Flaxman was in the habit of making drawings on the backs of the envelopes of letters received by him at Buckingham Street, Fitzroy Square, and a series of these, dating from about 1800 to 1814, is preserved in the British Museum. In every instance the pigment in these drawings is typical of pure graphite, and even interrupted striations are only of exceptional occurrence.

In view of the fact that Conté's composite clay process was invented in 1795 in Paris, it is interesting to note that a card sent to Flaxman by the painter Fleury Epinat, of Lyons, between 1805 and 1814 was written with a pencil producing the characteristic fine regular beaded striations of the modern type of pencil. This is the first instance noted of the occurrence of writing in a composition pigment in the MSS. in the Museum.

Of the other manuscripts and drawings of the early nineteenth century, mention may be made of a letter of Byron (about 1809) which is written in a particularly brilliant graphite, and of the pencil corrections made by Keats (about 1820) in his manuscript of "Hyperion," which are also in pure graphite. The same characteristics of rich pigment deposit, showing only scanty, irregular, broken striations, may also be seen in a letter of Lord Wellesley written about 1828.

The manufacture of graphite pencils by the original method of cutting from the block was continued until about 1869, overlapping the modern process; but, as the old pencils must have been widely distributed, it is not surprising that the characteristics of pure graphite are frequently to be found in writing, and especially in drawings, for several years after that date. Hence it is quite in accordance with the development of the industry that the note-book of James Thomson, the author of "The City of Dreadful Night," for the year 1869 should be written with a pencil which produced no silvery striations.

The Relationship of Education to Research in Aeronautics.

THE relation of education to research is a simple one in most fields of scientific work, in that the universities provide both one and the other. This simplicity cannot, however, extend to the subject of aeronautics, because the cost of experimentation is so great and the organisation required so complex. In the future the universities may perhaps be equipped even for this extension of their activities, but at the present time, and for many years to come, the experimental work will in general be beyond their means. The Government, however, for its own sake, needs to continue to carry on aeronautical research, and the question naturally arises: What are to be the relations between the Government research establishments and the university teaching establishments? The Committee appointed in October, 1918, by Lord Weir to advise on this matter has now reported, and its recommendation is to merge the staffs undertaking these two classes of work. At the present time it is scarcely practicable or wise to found more than one school of aeronautics, and the Committee selects the Imperial College of Science as its home, suggesting that the staff of the school should for the most part be composed of those members of the Government research establishments who are best qualified for the work, and can be permitted to spend part of their time at the Imperial College.

The Committee also provides that the Advisory Committee for Aeronautics should come to an end, and that its former powers should—with certain additions—be made over to a new body, the Aeronautical Research Committee. The Advisory Committee has had a very distinguished history. Its composition was mainly non-official, and it became a watchful and highly independent body able and ready to intervene in any matter where it thought such intervention was required. With the many reorganisations of Air Service matters during the war, whether relating to the R.N.A.S., the R.F.C., the Air Board, the Air Ministry, or the R.A.F., it became the one continuously operating body, and rendered services to the State of a value which can be realised only by those who kept in touch with its wide activities. The Education and Research Committee endeavours to pay tribute to the Advisory Committee, and it must have had some difficulty in finding words appropriate to the occasion.

It seems that the Government took definite decisions some six months ago that an Aeronautical Research Committee should be created to replace the existing Advisory Committee; that, in addition, research work should be undertaken by a Research Association to be formed by the Department of Scientific and Industrial Research, on the usual terms, if the industry should so desire; and that the Imperial College should be the educational centre (although applications from provincial universities for grants would be considered). The Committee, taking note of these decisions, suggests that the new Aeronautical Research Committee (A.R.C.) should supervise both research and education. Any plan for the supervision of research needs to take into account

the nature of the establishments where it is at present undertaken. These places are the Royal Aircraft Establishment (Farnborough); the National Physical Laboratory (controlled by the D.S.I.R.); Martlesham Heath, Biggin Hill, Pulham, Grain, Felixstowe, and possibly other Government aerodromes. All of these, except the R.A.E. and the N.P.L., are controlled by the Director of Research at the Air Ministry on behalf of the Air Council, which is responsible for these centres and pays for them. The Committee does not attempt to pursue the allocation of responsibilities further, but such allocation need not be expected to lead to difficulty, since much of the work from these centres found its way in the past to the old Advisory Committee, and will doubtless in the future find its way to its successor.

As regards the educational side, the Committee mentions an estimate that before the war the total yearly number of honours graduates in engineering, including civil, mechanical, and electrical, and in naval architecture, etc., from all the universities in the United Kingdom averaged only about two hundred, and that of these it rightly considers only a fraction of the future number are likely to devote themselves entirely to aeronautics. It certainly seems probable that the number will be quite small; the Government has its own Air Service establishments, and these will naturally take a proportion of the possible entrants each year. Moreover, the most promising career for aeronautical engineering work at present is the Government service, since it is the Government which controls nearly all the research and no small proportion of the full-scale design, to say nothing of the ordinary Service work and its attraction to the adventurous. The only factor which would seem capable under present conditions of adding materially to the numbers of students taking an aeronautical engineering course at the Imperial College or elsewhere would be if the Government used this means for the training of its own future technical staff.

The course, once formed, is to consist of twelve months' specialised teaching, coming after the usual degree or diploma course in engineering already provided at the universities and great technical schools. The subjects selected for this course are: Aerodynamics; aero-engines; general design; instruments, meteorology, and navigation. The proposed staff includes a general director, who would be the Zaharoff professor of aviation, two other professors, and a number of lecturers. This staff should, the Committee suggests, act as a clearing-house for the study of the results of experimental work, whether full-scale or in the laboratory, and for the dissemination of conclusions based thereon as forming the right foundation for further design. As the Committee naturally adds, no school for providing this education can be successful unless the students are brought into direct touch with practical problems during their tuition, and unless those engaged in teaching are also occupied in, or directing, scientific research or experimental design.

Some extracts from the Committee's report are subjoined.

INTRODUCTION.[1]

The Government has now decided how provision is to be made for research in aeronautics. We desire at the outset to emphasise the necessity for that research. The Department of Scientific and Industrial Research is to continue the provision for fundamental research at the National Physical Laboratory, and to assist the aeronautical industry in the same manner as other industries by taking part, when desired, in the formation of a research association. In our view, at the start of a new industry something more is required. At the present moment the industry is passing through a crisis; Government support is necessary if it is to emerge satisfactorily. The time is critical and the development of civil aviation is beset by numerous difficulties, and calls for the fullest consideration. It is urgently necessary that the policy adopted should command the support of all who desire to maintain the superiority in the air gained during the past eventful years, and that ample funds should be provided for carrying it into effect.

A difficulty which arises in the case of a new industry of this kind lies in the fact that the scope of the work is inadequate to maintain automatically a sufficient number of experts in design and production. A research organisation may elucidate problems and provide general information and specific facts, but before these can bear fruit of industrial value they must be interpreted and applied by a suitable technical staff, closely associated with the works organisation. At the end of the war most of the works had collected a team of technical experts of marked ability; many of these teams have now been disbanded, and further disintegration is in progress. We see no possibility of achieving the desired result except by such Government action as will secure the retention of adequate technical staffs.

During the war this country obtained the lead in aeronautical research; it would be lamentable to see the fruits of the work pass from a paralysed industry to better-supported foreign competitors. In the later sections of our report we recommend the establishment of an organisation for aeronautical research to assist the Air Council, and, in our view, it is important that the work of that organisation should be available in great measure for the assistance of the industry and for the advance of civil aviation, as well as for the Services. Should an industrial research association be formed, it should be linked up with the organisation we recommend.

Education and research are clearly very closely interrelated. The education with which we have chiefly concerned ourselves is that suitable for aeronautical engineers and constructors—that is to say, postgraduate work for which the students will be fitted by a previous undergraduate course of either mechanical or general engineering training at one of the universities or technical colleges. We have not dealt with the training of pilots or of mechanics. The course we contemplate will comprise a special study of the following matters:—Aerodynamics, the laws of motion of bodies moving in the air, illustrated by experiments and researches in wind-channels; the principles of design and construction; engines and the methods of propulsion of aircraft; and the inves-

[1] Abridged from the Report of the Committee on Education and Research in Aeronautics (Cmd. 554, price 2d. net) to Mr. Winston S. Churchill, Secretary of State for Air. The members of the Committee were: Sir R. T. Glazebrook, K.C.B (Chairman), Sir Alfred Keogh, G.C.B., Sir H. Frank Heath, K.C.B., Sir Francis G. Ogilvie, Mr. F. Handley Page, Mr. G. Holt Thomas, Prof. J. E. Petavel, and Lt.-Col. H. T. Tizard.

tigation of instruments used in flight, with problems in meteorology and navigation. The engineer must also gain the practical knowledge acquired only in the workshop, and must have experience of the full-scale researches necessary to test and verify his theoretical conclusions. Such a course might eventually involve one or more centres of theoretical instruction with experimental aerodromes and laboratories where the full-scale problems may be worked out, but as the number of persons likely to require this higher post-graduate education will not be great we consider that it will be wise for the present to concentrate the work in one central institution with which the experimental aerodromes should be closely connected. Such a central institution we find in the Imperial College of Science and Technology, at which the professorship lately founded by Sir Basil Zaharoff is to be held.

To turn now to research. This is the means by which advance in aeronautics is possible, and it is required by all interested in the progress of the subject: by the State, whether for the purposes of defence or to enable it to lay down the rules necessary for the safety of aircraft when used for civil purposes; by the professor, whose aim is to increase knowledge; and by the industry, in order that it may maintain the superiority which British aircraft has already achieved. Research is difficult, its requirements are costly, and the men who can undertake it are few. To establish separate research laboratories and aerodromes for each of these special interests is, for the moment, out of the question; here, again, combination is called for—combination, too, with the agencies concerned in education. At the same time we recognise fully that special problems may be dealt with at other research centres, and we trust that every encouragement may be given to these for such work.

Since the commencement of practical aeronautics, research has been directed by the Advisory Committee for Aeronautics, a body, under the presidency of the late Lord Rayleigh, appointed by the Prime Minister in the year 1909 "for the superintendence of the investigations at the National Physical Laboratory and for general advice on the scientific problems arising in connection with the work of the Admiralty and War Office in aerial construction and navigation."

Full-scale research has been carried out at Farnborough, in part at the initiation of the Advisory Committee, in part at that of the military authorities; the Committee, however, has no control over the work there, and occupies only an advisory position with regard to it. During the war other centres of full-scale research were established—*e.g.* the Isle of Grain and Felixstowe for seaplanes, Kingsnorth and Pulham for airships—and the Advisory Committee has been kept in close touch with the work in progress at all of these. Its activities have been of the greatest value. In our view, a central co-ordinating body of this kind is essential, and it is now proposed to establish an Aeronautical Research Committee, to which the duties of the Advisory Committee would be transferred, and certain other duties and responsibilities added with regard both to the central research aerodromes and to education. The proposed Committee should be in a position to supervise effectively such work as comes within its purview.

The work in aeronautics conducted at the National Physical Laboratory would also, usually, be undertaken on the initiation of the Committee, the expenditure for such work forming part of the budget of the Department of Scientific and Industrial Research.

In order to connect the Committee with the educational work and to render the opportunities of research at Farnborough and elsewhere available both to teachers and to students, we suggest that arrangements should be made between the Committee and the Imperial College for dealing with matters with which they are jointly concerned. In this connection, moreover, we suggest that it would be possible in a number of cases for members of the research staff to act as professors or lecturers at the college.

CONSTITUTION OF THE AERONAUTICAL RESEARCH COMMITTEE.

The Aeronautical Research Committee should include representation of (*a*) the Department or Departments responsible for (i) naval and military aeronautics, (ii) the regulation of civil aerial transport; (*b*) the Department of Scientific and Industrial Research, including direct representation of the National Physical Laboratory; (*c*) the aircraft industry; (*d*) the Imperial College; as well as (*e*) other members of scientific attainments. The chairman of the Committee should be an eminent man of science, and in a position independent of the Government Departments represented on the Committee. He and the other non-official members of the Committee should receive suitable remuneration.

FUNCTIONS OF THE AERONAUTICAL RESEARCH COMMITTEE.

It should be the duty of the Aeronautical Research Committee to devote itself to the advance of aeronautical science, and, with this object, in particular (1) to advise on scientific and technical problems relating to the construction and navigation of aircraft; (2) to undertake or supervise such research or experimental work as is proposed to the Committee by the Air Ministry, and to initiate any research work which the Committee considers to be advisable; to carry out such work itself or to recommend by whom the work should be carried out; (3) to take over complete responsibility for the Air Inventions Committee and for the Accidents Committee; (4) to promote education in aeronautics by co-operating with the governors of the Imperial College; (5) to assist the aeronautical industry of the country by scientific advice and research, and to co-operate with any research association that may be established; (6) to prepare for the approval of the Air Council a scheme of work and estimate of expenditure for the year, and to administer the funds placed at its disposal by the Air Council; and (7) to make reports from time to time to the Air Council.

CO-ORDINATION OF THE RESEARCH AND EDUCATIONAL ORGANISATION.

We have referred to the need for close association between the research and experimental work and the strictly academic portion of the higher education. No school for providing this education can be successful unless the students are brought into direct touch with practical problems during their tuition, and unless those engaged in teaching are also engaged in or directing scientific research or experimental design.

The arrangements whereby the student will divide his period of post-graduate instruction between work on books and at lectures and practical work at research stations should apply also in regard to the duties of the teaching staff. These should be such as to enable a professor or lecturer to spend part of his time in giving instruction at the Imperial College, while giving the rest to investigations at one of the research centres.

The School of Aeronautics should provide advanced instruction as regards aeroplanes, seaplanes, airships, and kite-balloons in (1) aerodynamics; (2) aero-engines and methods of propulsion; (3) design,

including structure and materials; and (4) instruments, meteorology, and navigation. It would follow, therefore, that certain of the professors or lecturers in each of these subjects will discharge double responsibilities (*a*) as members of the staff of the Imperial College and (*b*) as officers of the research organisation directed by the Aeronautical Research Committee.

The Interim and Final Reports of Special Committee No. 5 of the Civil Aerial Transport Committee contain much valuable information as to the organisation of teaching and research. One factor of importance which they emphasise is the need for a trained staff to act as a clearing-house for the co-ordination and dissemination of aeronautical knowledge in all its aspects. The Central School of Aeronautics should, in our view, serve this purpose.

The functions of the teaching staff of the School may be stated under four distinct, though closely related, purposes:—(*a*) To study, co-ordinate, summarise, apply, and extend the knowledge derived from the experimental work carried out by the individual workers at various experimental stations in this country and abroad. (*b*) To stimulate research by indicating what information is most urgently required and what line of attack is likely to prove most profitable. (*c*) To guide and encourage research by constructive criticism based on a careful study of past and current work in this country and abroad. (*d*) To impart this knowledge by personal teaching to a limited number of post-graduate students.

A similar clearing-house for current knowledge would be of value in any science, but for aeronautics it is, for the present, essential; for whereas in older sciences—physics, for instance—the bulk of the experimental data has, throughout the course of generations, crystallised into well-defined laws which form a framework ready to receive any new facts and a criterion by which their accuracy can be estimated, in aeronautics the facts are the result of the work of the last five or ten years, and the framework uniting them exists only in the minds of the few men who have been personally connected with the process of development.

Before the war the total available knowledge was small, and it was possible for the members of the Advisory Committee to keep all the facts in mind while devoting most of their time to other duties. They then provided the necessary co-ordinating factor. This is no longer possible, and the function could best be discharged by the staff of the School working under their director with the view of co-ordinating and making available all the knowledge in each branch of the work as existing at the moment.

For these reasons it is essential that the permanent staff of the Central School should be adequate both in numbers and in range of experience to the duties outlined above.

The subject of meteorology, including with it training in navigation and the use of instruments employed in flight, is one of great importance. The position, however, of the teacher of this subject must depend on the action taken with regard to research and inquiry into meteorological science generally. We have made provision in the estimates for a teacher in meteorological subjects closely connected with aeronautics who should combine this work with research at one of the experimental stations. His work would be brought into connection with the central meteorological establishment. We would add that, quite apart from the other interests concerned, we feel it our duty to press for the establishment of a properly equipped centre of teaching in this subject, the need for which has been felt for some years and is now acute.

Notes.

By a majority of seventy-five in a House of close on eight hundred Oxford has decided, for good or ill, that the Greek language shall no longer be a compulsory study for any of her *alumni*. In favour of the statute embodying this policy, which came before a full meeting of Convocation on March 2, speeches were delivered by Mr. C. Bailey, of Balliol College, Dr. Farnell, Rector of Exeter College, and Dr. David, Headmaster of Rugby. The opposition was undertaken by Mr. R. W. Livingstone, of Corpus, Mr. R. Carter, Headmaster of Bedford Grammar School, and Mr. John Murray, M.P., of Christ Church. The issue before Convocation was, perhaps, not quite so clear as it might have been; for it is probable that many voters thought that the rejection of the statute would have meant the perpetuation of the old form of Responsions, an examination which is allowed on all hands to be in need of radical reform. There is no doubt that in any case, whether the statute passed or was rejected, no attempt would have been made by the advocates of Greek in Responsions to make that language compulsory for passmen or for honours candidates in science or mathematics. But the feeling against compulsory Greek in any circumstances prevailed with the majority of voters, and Oxford has distinctly and definitely decided that, so far as she is concerned, the Greek language, however desirable as a study for specialists, is no longer to be considered a necessary element in a general education. The present vote may be taken as the final settlement of a keenly debated and long-protracted controversy.

The council of the Royal Society has decided to recommend for election into the fellowship of the society the following fifteen from the list of candidates:—Dr. Edward Frankland Armstrong, Sir Jagadis Chunder Bose, Dr. Robert Broom, Prof. Edward Provan Cathcart, Mr. Alfred Chaston Chapman, Dr. Arthur Price Chattock, Mr. Arthur William Hill, Dr. Cargill Gilston Knott, Prof. Frederick Alexander Lindemann, Dr. Francis Hugh Adam Marshall, Dr. Thomas Ralph Merton, Dr. Robert Cyril Layton Perkins, Prof. Henry Crozier Plummer, Prof. Robert Robinson, and Prof. John William Watson Stephens.

The King has been pleased to approve the appointment of the Right Hon. Sir Auckland C. Geddes, K.C.B., President of the Board of Trade, as his Majesty's Ambassador Extraordinary and Plenipotentiary in Washington. Sir Auckland Geddes was formerly demonstrator and assistant professor of anatomy in the University of Edinburgh; professor of anatomy, Royal College of Surgeons, Dublin; and late professor of anatomy, McGill University, Montreal. A year ago he was appointed to succeed the late Sir William Peterson as principal of McGill University, and he has now cabled his resignation of this post.

During the war little was heard of wireless telegraphy except that its use by unauthorised persons was entirely prohibited, but a great deal of pioneering research in the development of new methods and the

perfection of old was carried out. The oscillation valve in particular came to its own as a wave generator, an amplifier, and a detector, and wireless telephony passed from its experimental to its practical stages. The human voice is now heard across the Atlantic and from aeroplane to aeroplane. Notable advances have also been made in long-distance wireless telegraphy, especially in the directions of increased speed of transmission and carrying capacity of installations. It is mainly due to these improvements that, as announced in the *Times* of March 2, it has now been found possible to accept commercial messages to America at rates lower than the ordinary cable rates by as much as 4*d.* per word. A service on these lines was inaugurated on Monday last between the high-power Marconi station at Carnarvon and Belmar (New Jersey). High-speed automatic transmitters are employed, and the installation is duplexed so that messages can pass simultaneously in both directions.

A DEPUTATION representing the British Medical Association and the British Science Guild waited upon Mr. Balfour at the Privy Council Office on Tuesday, March 2, to urge that a sum of about 20,000*l.* should be set aside annually for the purpose of awards for medical discovery on the lines suggested in the report of the joint committee of the two bodies published in NATURE of January 8 (p. 488). The deputation was introduced by Sir Watson Cheyne, and its views were put forward by Sir Clifford Allbutt and Sir Richard Gregory. In 1802 the House of Commons voted Jenner a grant of 10,000*l.* in recognition of the national value of vaccination, and five years later made him a further grant of 20,000*l.* The proposal is that this precedent should be made the basis of an established system of awards for medical and scientific discoveries as just compensation for financial sacrifice commonly involved in producing them. The Medical Research Committee and the Department of Scientific and Industrial Research have funds from which grants are made to assist research, but they cannot offer reward or even recompense to the investigator who makes a notable discovery with or without any such aid. Organised work on particular problems is necessary, but its character is different from that of the creative genius, who must be left free to follow his own course wherever it may lead. Devotion to such research ought not to signify ultimate pecuniary loss when the results achieved contribute substantially to human welfare and progress, and a modern State may well accept the obligation to make reasonable provision for those who have thus enriched it. Mr. Balfour expressed himself in full sympathy with these views, and promised to put them before the Prime Minister, who, he reminded the deputation, had always been ready to give practical support to scientific work and to show his appreciation of its essential value in national life.

MUCH regret will be felt at the failure of the *Times* aeroplane, with Dr. Chalmers Mitchell as scientific observer, to complete the flight from Cairo to the Cape. On Friday last, February 27, a forced descent at Tabora, in the Tanganyika territory, due to the failure of one of the engines, damaged the machine beyond repair, and further flight with it has had to be abandoned. Fortunately, Dr. Chalmers Mitchell and his companions are safe, though two of them are hurt. Misfortune has followed the attempt from the beginning, owing chiefly to engine trouble. On February 20, soon after starting from Mongala, the starboard magneto cut out, and the aeroplane had to return there. Leaving later the same day, an unintended descent was necessary at Nimule, at the head of the Nile rapids. Then followed two comparatively short flights to Jinja, where the Nile leaves the Victoria Nyanza, and past the archipelago in the north-eastern part of the lake to Kisumu. The visit to Jinja probably enabled Dr. Chalmers Mitchell to settle the question whether the Ripon Falls, where the Nile discharges from the Victoria Nyanza, are due to a dyke of igneous rock, as has been often asserted, or to a hard band of gneiss. The next stage of the journey from Kisumu to the southern end of Lake Tanganyika was known to present new difficulties, but if these had been surmounted the rest of the route would have been near railways, along which there would be better facilities for repairs than between Khartum and the Victoria Nyanza. It is very disappointing that the disaster should have happened after the worst part of the journey had been traversed, yet we are confident that the observations made by Dr. Chalmers Mitchell in the course of his flight will abundantly justify the scientific purpose he had in mind in taking part in it.

WE much regret to see in the *Daily Express* of March 2 the announcement that Dr. C. Gordon Hewitt, Dominion entomologist, has died in Ottawa.

THE New York correspondent of the *Times* reports that Major R. W. Schroeder, chief test pilot at Dayton (Ohio), on February 27 ascended to the record height of 36,020 ft. (nearly seven miles) in an attempt to attain a height of 40,000 ft. At the former height the oxygen supply ceased to flow, and Major Schroeder fainted. He raised his goggles to see if the emergency supply was working. "All at once," he says, "it seemed as though a terrific explosion had taken place inside my head. My eyes hurt terribly. I could not open them. I seemed to be peeping through a crack. There was a tremendous rush of air, and I seemed to be falling. . . . I do not remember landing."

THE news of the death of the Rev. Watson Failes has been received with deep regret by Old Westminsters and many former colleagues who remember him with affection. Mr. Failes was a mathematical scholar of Trinity College, Cambridge, and graduated as nineteenth Wrangler in the year 1871. He was assistant master at Bromsgrove in 1874 and 1875, and at Dulwich from 1875 to 1877. In 1877 he went to Westminster School, where he remained for thirty years. On the retirement of Mr. Cheyne and Mr. Jones he became senior mathematical master, and in 1897 he became master of Rigauds. Mr. Failes was an enthusiastic and stimulating teacher; his own solutions, especially of purely geometrical problems, were models of lightness and elegance. He was the

author of "Solutions of Jones and Cheyne's 'Algebraical Exercises.'"

A GROUP of American botanical institutions and individuals has arranged through the Smithsonian Institution for the continuation of the lease of the Cinchona Station in Jamaica. Both British and American botanists are welcomed at Cinchona. Any British workers desiring to use the station should apply direct to the Jamaican Government. Local information could be obtained from Mr. William Harris, the Government Botanist, at Hope Gardens, Kingston, Jamaica. The opportunity of studying the peculiarly rich flora of the mountain forests is exceptionally good, while the station itself provides laboratory space. Not the least advantage to British students would be the intercourse with American students and the interchange of ideas which would naturally follow. The arrangements for American students are in the hands of a committee consisting of Dr. Britton and Profs. Coulter and Duncan Johnson.

THORSTEN NORDENFELT, whose death at Stockholm was recently announced, was best known as the inventor of the gun which bears his name and as the builder of a submarine. Gatling, Gardner, Hotchkiss, and Nordenfelt all achieved success with their machine-guns, but the greatest advance was made by Maxim, who first used the force of the recoil to work the mechanism. In the Nordenfelt gun the barrels were placed side by side horizontally, the firing mechanism being actuated by a lever moved to and fro by the gunner. A series of trials carried out at Portsmouth in 1880 led to the use of the Nordenfelt gun in H.M. ships for defence against torpedo-boats. In 1883 Nordenfelt constructed a submarine of about 60 tons displacement. The propelling machinery consisted of a compound surface-condensing steam-engine of about 100 h.p., the surface speed being nine knots. Steam generated while on the surface could be stored, and this was used for running short distances when the boat was submerged. The crew consisted of three men, and the boat carried Whitehead torpedoes. It was, however, as the inventor of the gun bearing his name that Nordenfelt was best known in this country, and the firm formed for the manufacture of the gun became amalgamated with the Maxim Co., and now forms part of the Vickers Co.

WE regret to see the announcement of the death of Mr. C. D. Leslie at Fortuna, Transvaal, as the result of a railway collision. Mr. Leslie was born in Ross-shire, Scotland, in 1871, and was educated at Fortrose Academy and George Watson College, Edinburgh. In 1889 he went to South Africa to take up a position with the Natal Civil Service, and six years later he left Natal to try his fortunes on the Rand. Here he acquired his practical knowledge of mining by working side by side with the miners, and his early experience gave him a great insight into underground working conditions and a profound knowledge of the miners. His first position on the Rand was that of contractor to one of the mines of the Central Mining group, after which he joined the Consolidated Gold Fields group, and became manager of the Jupiter, Nigel Deep, and Simmer and Jack Proprietary Mines, where his organising powers and general mining knowledge, gained in his early mining training, fitted him for the position which he ultimately held as consulting mining engineer to the Consolidated Gold Fields of South Africa, Ltd. During the time that Mr. Leslie held this position he interested himself considerably in improving general mining conditions, being, amongst other things, prominent in the organisation of the early trials on drill steels, and the interest he took in the mining industry was exemplified by the able address he made during his period as president of the South African Association of Engineers and by the scientific movement he initiated in 1916 to develop the industries of South Africa.

AT the forty-second annual general meeting of the Institute of Chemistry, held on March 1, Sir Robert Robertson, vice-president, occupied the chair in the place of Sir Herbert Jackson, the president, who was absent through illness. In moving the adoption of the report of council, Sir Robert read the president's address, in which reference was made to the position of professional men under prevailing economic conditions. The situation is far more promising than at the time of the armistice; more than 530 chemists whose names had been on the appointments register have now no further need of this assistance. The roll of the institute is steadily increasing, numbering nearly three thousand fellows and associates and more than five hundred registered students. The council has taken up the question of securing representation of chemistry in the Ministry of Health, with the satisfaction of seeing Sir William Tilden appointed a member of the Council of Medical and Allied Services, and Dr. J. F. Tocher Chemist to the Scottish Board of Health. Jointly with the Institute of Metals, a committee is engaged on questions affecting the status and organisation of chemists and metallurgists with the Navy, Army, and Air Force. The officers and members of council for the year 1920–21 were elected as follows:—*President*: Sir Herbert Jackson. *Vice-Presidents*: H. Ballantyne, Sir J. J. Dobbie, E. M. Hawkins, G. T. Morgan, Sir Robert Robertson, and G. Stubbs. *Hon. Treasurer*: E. W. Voelcker. *Members of Council*: W. E. Adeney, W. Bacon, E. C. C. Baly, O. L. Brady, F. H. Carr, A. Chaston Chapman, A. Cottrell, A. C. Cumming, J. T. Dunn, L. Eynon, A. Findlay, G. W. Gray, F. W. Harbord, C. A. Hill, P. H. Kirkaldy, J. H. Lester, W. Macnab, S. E. Melling, G. W. Monier-Williams, A. More, F. Mollwo Perkin, G. H. Perry, B. D. Porritt, F. M. Potter, J. Rogers, E. W. Smith, and W. M. G. Young.

AN important scheme for the co-ordination of the Health Department of Glasgow has been adopted by the City Council. Dr. A. K. Chalmers, the Medical Officer of Health, will be the head of an enlarged health department, which will now include the sanitary inspector, the veterinary surgeon, and the bacteriologist, each of whom until now has been head of a separate department and largely independent of the others. It can scarcely be doubted that this arrangement will conduce to efficiency and economy.

THE first of three Chadwick public lectures on "Military Hygiene in Peace and War" will be delivered by Gen. Sir John Goodwin, Director of the Army Medical Department, on Monday next, March 8, at 5.15 p.m., in the lecture-room, Royal Society of Arts, John Street, Adelphi, W.C.2. Immediately preceding the lecture Chadwick gold medals and prizes for services in promoting the health of the men of the Navy and Army will be presented to Surg.-Comdr. E. L. Atkinson, R.N., and Brig.-Gen. W. W. O. Beveridge, A.M.S.

AN extremely interesting account of the nesting habits of the storm-petrel by Mr. Audrey Gordon appears in *British Birds* for February. The author's notes were made during a brief stay on one of the smaller islands of the Inner Hebrides. Of the courting habits of this bird nothing is known, but the author believes that certain weird noises uttered while on the wing during dark and stormy nights or when the nights were misty are to be regarded as part of the courtship performances of the males. During this time the birds would seem to be circling round the nesting area at a great pace, like nocturnal swifts. While this is going on an incessant "purring" can be heard from the birds, which were probably the females, ensconced in rocky crevices. Mention is made of the bare patch on the crown of the nestling. This deserves closer investigation. It is found also in the young ostrich and in the nestling of the great crested grebe, where it takes the form of a vermilion heart-shaped prominence.

IN the Annals of the Royal Botanic Gardens, Peradeniya (vol. vii.), Mr. T. Petch continues the publication of his work on the fungi of Ceylon. "Revisions of Ceylon Fungi," part vi., embodies a critical examination of a large number of species and the correlation of the specimens in the original collections of Thwaites in Ceylon with those sent by Thwaites to Berkeley and Broome, now at Kew and the British Museum respectively, from which the species were described. Incidentally, an interesting question arises as to which series is to be regarded as containing the type-specimens. A second paper, "*Gasteromycetae zeylanicae*," contains a list of these larger fungi, including those originally recorded by Berkeley and Broome, as well as more recent additions. A full account of one of these, a remarkable phalloid form, which the author has studied in detail, appears in the Transactions of the British Mycological Society (vol. vi., part ii.), where it is described as the type of a new genus, Pharus.

THE Annals of the Royal Botanic Gardens, Peradeniya (vol. vi., part iv.), contains an account, by Mr. G. Bryce, of the structure and development of the small woody "burrs" or "nodules" which are found in the cortex of the rubber-tree, *Hevea brasiliensis*. The nodules increase from the size of a pea to that of a hen's egg, and may sometimes produce large sheets of woody tissue. As they grow larger the stem becomes gnarled and warted, the cortex cracks and latex oozes out, and the tree becomes useless for tapping. These nodules occur only on trees which have been tapped, and appear to be the result of physiological changes, the nature and cause of which are at present unknown, in the contents of the latex-vessels. They are formed round altered latex-vessels or round lesions or areas in the cortex into which latex has oozed and coagulated. The tendency to nodule formation appears to be confined to certain predisposed individual trees, and this abnormal condition is apparently not infectious. The nodules in Hevea are somewhat similar in structure to the isolated woody nodules which occur in the cortex of beech, pear, and apple. They consist of a central dark brown core, appearing as a point or line, of cortical elements, surrounded by a zone of wood derived from cambium and forming the bulk of the nodule. They are quite distinct from the globular woody shoots, such as are well known in beech, and are formed by the subsequent growth of dormant buds which have lost their original connection with the woody cylinder of the stem. These occur in both tapped and untapped trees of Hevea, but never form large masses of woody tissue as do the nodules.

A CATALOGUE of meteorological instruments has just been issued by Messrs. C. F. Casella and Co., Ltd., of Westminster. It is interesting to see the return of pre-war activity in this direction; necessarily a largely increased cost has occurred in the manufacture of the instruments, ranging from 33 to 75 per cent. Full details are given of the respective instruments, and there is much information as to the placing and the exposure required by meteorologists to render the observations of scientific value. Many may require the instruments only for casual use, but occasions will occur when the observations may be of real value to meteorologists. The catalogue gives a large range of choice with regard to price, and without doubt even the cheaper instruments noted are trustworthy. From a scientific point of view a mercurial barometer should be preferred to an aneroid. In the class of thermometers, perhaps a Six's maximum and minimum thermometer should be less preferable than the more ordinary maximum and minimum thermometers; experience has proved it to be more liable to get out of order. Referring to terrestrial radiation thermometers, it is recommended that the instrument should be placed at a height of about 2 in. above short grass; to fall into line with the recommendations of the Meteorological Office, the bulb of the thermometer should just touch the blades of short grass. Good illustrations are given of the various self-registering instruments, and the catalogue affords an easy means of selecting an outfit for all meteorological purposes.

IN the December, 1919, issue of *Terrestrial Magnetism and Atmospheric Electricity* the editor, Dr. L. A. Bauer, directs attention to the difficulties raised by the directors of magnetic and electrical observatories who do not carry out the decisions as to the observations and their reduction arrived at after adequate discussion at meetings of the International Commission on Terrestrial Magnetism and Atmospheric Electricity. Although at the Innsbruck meeting of the Commission in 1905 it was resolved without any dissentient that future tabulation of the

magnetic elements should be in Greenwich time, no British observatory outside Great Britain has carried out the decision. With the view of securing uniformity, Dr. Bauer invites discussion of the following questions: Shall Greenwich time or the nearest standard meridian time be used for the magnetic records? Shall the mean value of an element be taken from a full hour to the next or from a half-hour to the next half-hour?

AT the meeting of the Illuminating Engineering Society on February 24 a discussion on "Lighting Conditions in Mines, with Special Reference to the Eyesight of Miners," was opened by Dr. T. Lister Llewellyn, a considerable number of members of the Council of British Ophthalmologists and of the Ophthalmological Section of the Royal Society of Medicine being present. The introductory paper dealt largely with the disease of the eyes known as "miners' nystagmus," the increase in which has given much concern in recent years. The disease is common in coal-mines, but practically unknown in metalliferous mines. Dr. Llewellyn, by the aid of statistics on eyesight, supplemented by data on the actual working illumination in mines, contended that the disease was mainly due to inadequate illumination; while Dr. H. S. Elworthy adduced data to show that the colour of the reflected light, depending chiefly on the nature of the coal-surface, was also an influential factor. Medical men from various mining districts emphasised the complexity of the problem, but there was general agreement that illumination and the dark nature of the reflecting surface in coal-mines were important factors. A variety of types of miners' lamps were exhibited, and Mr. E. Fudge, secretary of the Home Office Committee on Miners' Lamps now sitting, made some remarks on possible developments. The question of whitewashing coal-surfaces in order to improve the reflection of light was also considered. At the conclusion of the discussion Mr. L. Gaster suggested a comprehensive investigation by competent photometric experts, aided by ophthalmic surgeons, in order to obtain data on a uniform basis, establish the nature of the conditions of illumination to be guarded against, and consider possibilities of meeting lighting requirements.

AN interesting paper on the theory and practice of lubrication was read by Messrs. Wells and Southcombe before the London Section of the Society of Chemical Industry on February 2. Free fatty acids in lubricants have hitherto been judged mainly by the injurious effects which they are capable of causing. It has now been found, however, that these acids, in strictly limited amount, can greatly increase the value of mineral oils as lubricants. Tested in a Thurston friction machine under conditions of very low speed and high pressure, it was found that 0·5 per cent. of the fatty acids of rape-oil added to a mineral oil reduced the friction coefficient from 0·0066 to 0·0049, whilst nearly 60 per cent. of the same rape-oil free from acid was required to produce the same effect. It appears, therefore, that this discovery affords the means of diverting to other and more useful purposes the greater part of the saponifiable oils and fats now used for blending with mineral oils.

IN a paper read to the Institution of Petroleum Technologists on February 17, Dr. W. R. Ormandy describes a number of patents which have been taken out for mixtures intended to be used as motor fuels. Protesting against the present system, he states that patents have been granted for admixtures of bodies which every chemist knows will mix, and every engineer knows will drive an internal-combustion engine. Many of them are certainly not inventions or discoveries. Presumably the patents have been granted because the patent records of the preceding fifty years cannot show that anything of the sort has previously been patented. But it is common knowledge to those skilled in the matter that such liquids as paraffin, petrol, benzol, alcohol, ether, and acetone will mix either in any proportion or in restricted proportions; and also that by admixture, for example, of petrol with benzol a certain amount of alcohol can be caused to dissolve in the mixture which would not dissolve in the petrol alone. It is equally common knowledge to chemists and engineers that any admixture of two or more volatile fuel bodies will result in a third substance also capable of being used as a fuel. Disclaiming any intention of expressing a pronounced opinion on any of the specifications, the author regards it as prejudicial to the general interests of the community that such patents should exist, and has no doubt that they contain the seeds of many lawsuits.

WE have received from Messrs. Flatters and Garnett, Oxford Road, Manchester, their price-list of stains, chemicals, slides, cover-glasses, dissecting instruments, etc., for use in microscopical and histological work. The list of stains, which are all tested, seems fairly complete, and the solids are supplied in quantities of 2½, 5, 10, and 25 grams. With a selection of this kind to choose from, the worker in these branches of science should be independent of foreign supplies.

Messrs. Methuen and Co., Ltd., will publish shortly a translation by Mr. R. W. Lawson, of the University of Sheffield, of "The Special and the General Theory of Relativity," by Prof. Einstein. The volume is primarily intended for those who are not conversant with the mathematical analysis used in theoretical physics, the aim of the author being to give the main ideas of the theory of relativity in the clearest and simplest form.

A COURSE of lectures was delivered in the University of London in 1913 by Prof. E. Bresslau, of the University of Strassburg, and a volume based on them, bearing the title of "The Mammary Apparatus of the Mammalia in the Light of Ontogenesis and Phylogenesis," with a preface by Prof. J. P. Hill, is to be issued by *Messrs. Methuen and Co., Ltd.*, this spring. It will provide an epitome of Prof. Bresslau's investigations on the development of the milk-glands and related parts in the mammalia, and of his conclusions respecting the evolutionary history of the mammary apparatus, and be fully illustrated.

Our Astronomical Column.

OCCULTATION OF A STAR BY SATURN.—Mr. A. Burnet has pointed out that the star Lalande 20654 (mag. 7·3) will be occulted by Saturn on the evening of March 14. Mr. L. J. Comrie gives some further details and a diagram in the Journal of the British Astronomical Association for January. At Greenwich the star disappears at 7h. 5m. in position angle 281°, just to the north of the ring, reappearing at 8h. 40m. in angle 121°. The star will pass very close to Titan about 12h. 15m., and an occultation by that satellite will probably occur somewhere on the earth; hence it is important to observe the conjunction with care, and, if an occultation occurs, to take the times of disappearance and reappearance, as a useful determination of Titan's diameter might be made from such observations. A central occultation would last about five minutes.

THE NAUTICAL ALMANAC FOR 1922.—This volume has lately been issued, and is of interest as being the last almanac in which the places of the moon are based on Hansen's tables; these were first used in the 1862 almanac, but, starting with 1883, Newcomb's corrections have been applied to them. For ten years after this the errors of the almanac places of the moon were very small, then they began to mount up, and now reach nearly 1 sec. in R.A. The introduction of Brown's tables in the 1923 volume will greatly reduce this error, but will not remove it entirely, since Dr. Brown has preferred not to introduce a term of some sixty years' period which is indicated by the observations.

CALENDAR REFORM.—This question, which was suspended during the war, is again coming to the front. The majority of the reformers agree on the following points:—(1) That each quarter should have ninety-one days (thirteen weeks), there being two months with thirty days and one with thirty-one, these lengths repeating themselves in the same order in each quarter; (2) that one day in each year, and a second day in leap year, should stand outside the week, so that the week-days repeat themselves alike in every year; and (3) that the leap day should come at the end of the year, its position in the second month being extremely inconvenient. Mr. Alexr. Philip proposes to begin the year with March, thus restoring the meaning of the names September, etc. He further suggests that the day outside the week should be Whit-Sunday, which is put at the end of the first quarter (May 31); it is immediately followed by an ordinary Sunday, taking advantage of the fact that the day following Whit-Sunday is already a general holiday. Easter Sunday on this plan would always be on April 12. The leap day would come as now, at the end of February, but this would then be the last month of the year. He further suggests that, if it be desired to keep the months as nearly as possible at their present lengths, his scheme would involve no greater change than that August should give one day to February.

M. Flammarion's scheme, reprinted in the *Annuaire Astronomique* for 1920, is similar, but more revolutionary. He would begin the year at the vernal equinox, giving new names to all the months. Their lengths in each quarter would be 30, 30, and 31 days. Easter would be the 21st of the first month (corresponding with April 10). The extra-week day and the leap day would both come at the end of the year.

It would seem desirable that all reformers should agree to adopt one of the many schemes that have been proposed, as unanimity is required to give sufficient driving power to carry any reform. The fact that the present most illogical calendar has survived so long is a forcible illustration of the strong conservatism of mankind.

The Association of Technical Institutions.

THE twenty-seventh annual general meeting of the Association of Technical Institutions was held in the Cordwainers' Hall, E.C., on Friday and Saturday last, February 27 and 28. The meeting was opened by the retiring president, Lord Sydenham. The Marquess of Crewe, K.G., was elected president for the year 1920, and delivered his inaugural address, in which he dealt at length with the working of the Education Act of 1918, especially in its relation to continuation schools, and went on to plead strongly for better education and training in the science and methods of agriculture, certainly our oldest, and possibly our largest and most vital, industry. No industry demands for its successful prosecution a sounder knowledge of the various sciences, including chemistry, botany, geology, bacteriology, entomology, meteorology, and engineering. Modern agriculture is a complex business, and measures should be taken for the due training of all concerned, whether engaged in it on a small or a large scale, and especially in the scientific study and practice of forestry. One of the fruits of the great war was seen in the newly awakened interest of employers in the applications of science to industry, and in their greater readiness to find appointments and opportunities for students who, on the foundation of a good general education, had specialised in scientific subjects and showed themselves willing and able to undertake important research. In this regard we could learn valuable lessons from American practice. It was gratifying to observe also the keenness displayed by the general class of workers, who, under the auspices of the Workers' Educational Association, are now, with shorter traditions and scantier leisure than other social classes, interesting themselves in liberal studies relating to literature and history, and in social and political economy. It is all to the good in the building up of an educated nation.

The report for the year 1919 was submitted, showing that the membership of the association now comprised 108 institutions, the highest in its history, being an increase of ten over that of 1914. Steps have been taken to bring before the Board of Education the necessity for providing not only facilities, either in full-time or vacation courses, for persons desiring to become teachers in the new continuation schools set forth in the Education Act of 1918, but also opportunities for present continuation-school teachers who need further training in this special form of educational work. It was suggested by the council that full-time courses might be of one year's duration or not shorter than six months, and that in the event of approved teachers so devoting themselves the Board might consider favourably the question of granting a maintenance allowance for such teachers. The council was assured of the sympathy of the Board in this matter, especially in the case of demobilised officers, and that a maintenance allowance would be made.

The question of pensions for teachers in technical institutions had also been considered and information thereon sought from the Board, which states that, with the approval given by the Treasury, the following will be accepted as counting for *qualifying* service, namely, in private schools (prior to April 1, 1919), provided they are conducted on the same standards of efficiency as schools under public management; as inspectors of schools under any Government Department in England, Scotland, or Ireland; as officials of the Board of Education or of the Scotch or Irish Education Department; as officials of a local education authority whose salaries are paid out of the education rate; as officials of any school or educational institution (not conducted for private profit), including a university, if the institution is one, teaching service

in which would be regarded as recognised and qualifying service; in the case of trade or commercial instructors, five years of practical experience or not more than seven years in special cases; in any university or university college; in any school receiving grants provided by a Government Department; as a supplementary teacher in a public elementary school; in any school in any British Colony or Dependency or in India, aided or under regular inspection by the Government; in any foreign country where there exists an arrangement for the interchange of teachers made by the Board of Education.

The question of salaries for teachers of various grades in technical institutions had been carefully considered, and the following scale was submitted to, and approved by, the meeting, and ordered to be forwarded to local education authorities and the governing bodies of technical institutes for their consideration, namely: Principals in four grades of schools ranging from 1250*l.* down to 500*l.*, and rising by annual increments during five years to 1500*l.* and 750*l.*; heads of departments in three grades ranging from 600*l.* down to 400*l.*, and rising by annual increments during ten years to 900*l.* and 600*l.*; heads of junior technical and commercial schools to be classed as heads of departments; lecturers in three grades ranging from 400*l.* down to 250*l.*, and rising by annual increments during three years to 600*l.* and 400*l.* respectively.

In a paper by Mr. A. Mansbridge on "Technical Schools and their Part in Adult Education," it was urged that a great crusade against the unworthy use of leisure is a pressing need of the time. There can be no better way for the worker to tread in his off-hours than that which leads to the development of his interests or his skill. Technical training can, however, never flourish in a community which does not regard the matters with which it deals as of fundamental importance to the whole health of man. A nation which merely regards it as a means of outstripping others must always be content with superficial achievement. The education of a man lies deeper than the pursuit of knowledge or training. Some turn to the influencing or contemplation of the ideas and movements of men, others to the creation of material things, and each alike serves his generation if the direction be true. Mr. Mansbridge pleaded that the technical institutes should make provision for adult men and women to study in their leisure time the matters, technical or non-technical, in which they are interested, or rather for which they possess the necessary aptitude. He asked that serious attention should be given to the notable Report of the Committee on Adult Education issued in July last.

A paper was read on "Day Continuation Schools" by Mr. H. J. Taylor, of Dewsbury, in which he urged that a hearty response should be given to the invitation of Mr. Fisher to local education authorities to establish these schools voluntarily on the lines laid down by the Board of Education in its recent circular, namely, that such schools must give as great a measure of liberal education, both physical and mental, as opportunity and time afford. Mr. Taylor contended that the most effective way in which the conditions could be met was by arranging for a complete day each week for groups of boys and girls, and cited the efforts of the Dewsbury Education Committee and of the employers of the town (without reducing the wages of their employees) to establish such a school as illustrating its possibility.

A further paper was read by Dr. R. S. Clay, of the Northern Polytechnic, London, in which he advocated an ampler provision of scholarships throughout the whole sphere of education by the institution to each ten thousand of the population of six junior scholarships from elementary to secondary schools, six industrial scholarships, three intermediate scholarships to enable the recipients to continue their education at the secondary school until the age of eighteen or nineteen, one senior scholarship to the university or the technical institute, and one post-graduate or research exhibition tenable at the close of the graduate course.

Resolutions were adopted dealing with lengthened vacations, so that teachers of special subjects should have facilities for keeping in touch with industrial developments; maximum teaching hours for ordinary lecturers and heads of departments; the appointment of a consultative committee comprised of representatives of industry, and including representatives of universities and technical institutions, to advise the university and technological branches of the Board of Education on all matters affecting the relationship of university and higher technical education to industry; and, finally, the provision that should be made in the preparation of schemes required by the Education Act of 1918 for the continuation of study on the part of science teachers by means of suitable tutorial courses of science lectures and practical work, together with facilities to attend meetings of scientific and technical societies and to visit special educational centres and industrial works.

The Einstein Deflection of Light.

THE idea of detecting the Einstein deflection by measures of two neighbouring stars has occurred to many people, and Prof. C. V. Raman writes to suggest that the apparent distance of the two components of a binary star may be influenced by the effect. It seems, therefore, worth while to examine the conditions, and to try to discover whether any sensible effects are to be expected.

First, it is easy to show that where the linear distance between the two stars is small compared with their distance from the sun, then the angular shift of the further star, due to the Einstein effect, is diminished as seen from the sun in the approximate ratio: Distance between the stars/their distance from the sun. That is, it becomes absolutely evanescent, and the effect suggested by Prof. Raman is non-existent.

Secondly, let the two stars be at different distances from the sun; for simplicity, take the distance of the

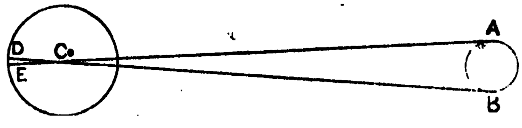

FIG. 1.—To illustrate the production of an image of a distant star by the gravitational bending of its light by a nearer one.

nearer star as half that of the further; let their angular diameters be 0·002″ and 0·001″ respectively, and let the angular distance between them be 1″. Then the light from the further star passes the nearer star at a distance of 1000 of its radii. If the bending of a grazing ray be 2″, the bending in the actual case is 0·002″, and the apparent shift as seen from the sun 0·001″. It appears that in no case where the two star-discs are sufficiently far apart to be easily separable is the Einstein shift appreciable.

A second Einstein effect has been imagined, viz. the formation of an image of the distant star on the reverse side of the nearer one. From C, the centre of the latter, draw tangents CA, CB, and produce them backward to DE. Then DE is one-millionth of a second. Now it is only along the arc DE that the Einstein image is produced, and the radial diameter

of the image can easily be shown to be of the same order as DE; whence the angular area of the image is, say, one-millionth of the area of AB; and since no optical arrangement can increase the surface brilliancy of an image, the latter is fifteen magnitudes fainter than AB, and therefore utterly invisible.

It is only when two stars approach each other so closely that their discs are almost in contact that any sensible Einstein effect occurs; and since the two discs are in this case absolutely inseparable, the visible effect would be simply a slight brightening. In view of (1) the rarity of such close appulses, (2) the impossibility of predicting them, and (3) the transient nature of the brightening, which would last for only a few days, the prospect of detecting such a phenomenon is very small.

The outburst of novæ cannot be explained in this manner, as some have suggested, for it could not possibly produce a ten-thousandfold increase in light; moreover, the light-curve before and after maximum would be exactly symmetrical, which is assuredly not the case with novæ, the increase of light being much more rapid than the decline.

It is to be noted that even if some brightening were observed in an appulse, it would be impossible to say whether the light-bending followed the Newtonian or the Einstein law.

A. C. D. CROMMELIN.

The New Zealand Institute.

THE publication of the fifty-first volume of the Transactions and Proceedings of the New Zealand Institute marks the commencement of a new epoch in the history of that very vigorous scientific organisation. The volume itself compares very favourably with those of past years, and its contents show that there is at least one part of the British Empire where pure science is being cultivated as strenuously as before the war. We are glad to see that the institute is receiving more support from the New Zealand Government, while the large membership of the nine constituent societies scattered throughout the Dominion clearly indicates the influence which it is exerting upon the New Zealand public.

The volume opens with obituary notices and portraits of three distinguished New Zealanders—Alexander Turnbull, who devoted his leisure to the collection of a magnificent library, bequeathed to the Dominion, including 32,000 bound volumes, dealing especially with the history of the Pacific Islands; Henry Suter, known throughout the scientific world as a distinguished student of conchology, and author of the "Manual of the New Zealand Mollusca"; and Thomas Adams, who did great work for his adopted country in the promotion of scientific arboriculture.

Of the numerous original memoirs which the volume contains, it is not too much to say that they embody a large amount of information of high scientific value, and if they relate almost exclusively to matters of local interest, dealing chiefly with the fauna, flora, and geology of the islands, this is only as it should be, for it is in these fields that the New Zealand man of science finds his magnificent opportunities. Where there is so much to choose from it is difficult to single out particular contributions for notice, but the attention of zoologists should be directed to the very interesting discovery of a second species of New Zealand frog, *Liopelma Hamiltoni*, found by Mr. Harold Hamilton on Stephen Island, in Cook Straits, and described (with excellent coloured illustrations) by Mr. A. R. McCulloch, of the Australian Museum. This species is closely related to the long-known but rare *Liopelma Hochstetteri* of the North Island, the only previously known New Zealand amphibian. In the botanical field Dr. J. E. Holloway continues his admirable studies on the genus Lycopodium, while geology is well represented by papers by Dr. P. Marshall, Mr. R. Speight, and others. In the department of geophysics Mr. A. W. Burrell contributes a very interesting account of a working model to demonstrate the manner in which ocean currents may be caused by the rotation of the earth.

In conclusion, we may note that the institute has decided to elect a body of fellows, limited to forty in number, who are to have the privilege of writing after their names the letters F.N.Z.Inst.—a distinction which we do not doubt will have a real value in the world of science.

The Geology of the West Indies.

EARLY in 1914 Dr. T. Wayland Vaughan, of the United States Geological Survey, paid an official visit to several of the smaller West Indian islands, partly with help from the Carnegie Institution of Washington. Besides studying the stratigraphical geology of the islands and making notes on their physiography, he also collected large series of fossils which were sent for detailed examination to Washington. He thus obtained material for a valuable contribution to our knowledge of the Tertiary sedimentary rocks which form the greater part of these islands, and made possible satisfactory comparisons with the corresponding geological formations of the southern United States. Dr. Vaughan has already published several preliminary notes on his results, and an especially important memoir on some fossil corals and the formation of coral-reefs. His final report, however, on the details of local geology and the general conclusions are deferred until all the fossils are examined and described. He has just edited a series of these descriptions, which has been published by the Carnegie Institution (Publication No. 291, 1919) in a small volume illustrated by beautiful photographic plates.

Calcareous algæ from the Eocene limestone of St. Bartholomew and from the Oligocene limestone of Antigua and Anguilla are described by Mr. Marshall A. Howe. Lithothamnium and related forms are well illustrated by enlarged sections. The Foraminifera are not only described with excellent figures by Mr. J. A. Cushman, but also discussed from the geological point of view. Some of the larger orbitoid species make correlations possible with corresponding rocks both in continental America and in Europe, while the small Miocene species allow very definite correlations with Panama and the coastal plain of the United States. The Bryozoa, described by Drs. F. Canu and R. S. Bassler, are of Upper Oligocene and Lower Miocene age, and notes are added on the distribution of those species which occur in other parts of the world. The Eocene and Oligocene mollusca, described by Mr. C. W. Cooke, are of great geological importance, and comparisons are facilitated by faunal lists. The account of the Decapod Crustacea, by Miss Mary J. Rathbun, is almost entirely new, only two species of one genus (Ranina) having previously been recorded from the Tertiary formations of the West Indies. A few genera are distinctively American, but some have close affinity with those at present living in the Indo-Pacific region.

We congratulate Dr. Wayland Vaughan and his colleagues on the thoroughness with which they are accomplishing their task, and we look forward to the publication of the concluding sections of this great contribution to the geology and palæontology of the Central American region.

University and Educational Intelligence.

BELFAST.—Dr. James Small, lecturer on botany in Bedford College, London, and in the London School of Pharmacy, has been appointed professor of botany in succession to Prof. Yapp.

CAMBRIDGE.—It has already been announced that a friend of Girton College has given 10,000*l*., to be applied, both capital and interest, during the next twenty years for the encouragement of research by women in mathematical, physical, and natural sciences. We now learn that a fellowship of the value of 300*l*. a year is offered by the college for research in such sciences as chemistry, electricity, engineering, botany, geology, medicine, agriculture, etc. The election of the fellow will take place in time to permit of the award by the council being made not later than June 30. Women who are graduates or have taken honours in a final degree examination of any university, and members of the Girton College Roll, are eligible for the fellowship. The fellow will be elected for three years in the first instance. Applications for the fellowship must be sent to the secretary of the college on or before March 31. Each candidate should describe a course of research and submit a dissertation or published work, in addition to any other evidence she may desire to furnish of her fitness to undertake the proposed course of research.

LONDON.—The Senate has received two letters from Viscount Haldane of Cloan, chairman of the Sir Ernest Cassel Educational Trust, offering important gifts in connection with the new degrees in commerce. The trustees offer an endowment of 150,000*l*. in War Loan, producing 7500*l*. a year, for the provision of eight, or possibly more, teaching posts in banking and currency, foreign trade, accountancy and business methods, transport and shipping, industrial organisation, and commercial law, and propose that these should include three Sir Ernest Cassel professorships in banking and currency, foreign trade, and accountancy and business methods respectively. They further suggest that the teaching in all the above-named subjects should be given at the London School of Economics, it being understood that accommodation for increased teaching is to be provided in the new buildings now being erected at the school, with the assistance of the sum of 50,000*l*. recently given by the General Committee for Degrees in Commerce, on the new site granted by the London County Council. The trustees also offer to allot to the University an annual grant up to 3000*l*. a year, for five years in the first instance, for the provision of additional instruction in the following modern languages required to meet the needs of students in commerce: French, German, Spanish, Portuguese, Italian, Russian, and Arabic, together with a further sum of 1000*l*. for the current year to meet the expenditure on additional modern-language instruction incurred during this year. They also place at the disposal of the University a sum of 1000*l*. a year, in the first instance for five years, for travelling scholarships for the benefit of students in commerce. The offers have been accepted by the Senate, and the Vice-Chancellor has been asked to convey to Sir Ernest Cassel and to the chairman of the Cassel Trust "the warmest thanks of the Senate for these great gifts for the cause of education, from which they anticipate the most fruitful results."

Dr. James McIntosh has been appointed as from March 1 to the University chair of pathology tenable at the Middlesex Hospital Medical School. During the war Dr. McIntosh carried out investigations at the Royal Herbert Military Hospital, Woolwich, on cerebro-spinal fever, and at the London Hospital on gas-gangrene. For the last nine months he has been a full-time investigator on the staff of the Medical Research Committee. Dr. McIntosh is the author of numerous reports and other articles in medical and scientific journals.

Dr. Sidney Russ has been appointed as from March 1 to be the first incumbent of the Joel chair of physics tenable at the Middlesex Hospital Medical School. The work of this professorship, recently established by the munificence of Messrs. S. B. and J. B. Joel, will deal especially with physics in relation to medicine. From 1906 to 1910 Dr. Russ was demonstrator in physics at the University of Manchester, and was appointed physicist to the Middlesex Hospital in 1913. He is the author of a large number of articles and other papers dealing with radio-activity and other aspects of medical physics.

The following have been appointed fellows of University College:—Mr. F. J. F. Barrington, assistant surgeon, Surgical Unit, University College Hospital; Mr. W. C. Clinton, assistant professor in the department of electrical engineering and Sub-Dean of the college faculty of engineering; Miss Ethel M. Elderton, Galton research fellow in the department of applied statistics and eugenics; Dr. T. H. C. Stevenson, superintendent of statistics at the General Register Office, and fellow and joint secretary of the Royal Statistical Society; and Dr. Ethel N. Thomas, lecturer in the department of botany, and keeper of the department of botany in the National Museum of Wales.

The degree of D.Sc. (Economics) has been conferred on Mr. W. Rees, an internal student, of the London School of Economics, for a thesis entitled "An Agrarian Survey of South Wales and the March, 1284–1415."

On Wednesday next, March 10, at 5.30 p.m., Lord Moulton will deliver an address at University College on "The Training and Functions of the Chemical Engineer." Prince Arthur of Connaught will preside.

OXFORD.—The King has been pleased to approve of the appointment of Sir Archibald E. Garrod, K.C.M.G., F.R.S., to be Regius professor of medicine in the University in succession to the late Sir William Osler, Bart.

THE fellowship diploma of the Royal College of Science for Ireland has been awarded to Mr. Hugh Ramage and Mr. R. L. Wills.

MR. W. D. EGGAR will deliver a course of four public illustrated lectures on "Optics" at Gresham College, Basinghall Street, E.C.2, at 6 o'clock, on March 9, 10, 11, and 12, in place of the course announced for delivery by the Gresham professor of geometry, who is suffering from illness.

THE Master and fellows of Corpus Christi College, Cambridge, propose to elect in July next a holder of the Almeric Paget studentship in political science, economics, and kindred subjects. The studentship is of the value of 150*l*., and tenable for one year. Applications should be addressed to Mr. W. Spens, Corpus Christi College, Cambridge, by, at latest, July 1.

THE next of the series of lectures for teachers on "Recent Developments in Science," arranged by the Education Officer of the London County Council, will be on "The Dye Industry," by Prof. G. T. Morgan, and will be delivered at Finsbury Technical College, Leonard Street, City Road, E.C.2, on Saturday, March 20, at 11 a.m. The chair will be taken by Dr. M. O. Forster.

H.R.H. PRINCE ARTHUR OF CONNAUGHT will preside on March 19 at a luncheon to be held at the Savoy

Hotel, when the proposals for the reconstruction and re-equipment of the engineering laboratories at University College, London, will be explained by the treasurer, Sir Ernest Moir, and others. It will be remembered that an appeal for 100,000*l.* towards this object was recently issued. Already more than 33,000*l.* has been collected—that is, about one-third of the total sum required. It is urgently necessary that the whole fund should be subscribed by June at the latest, in order that the buildings may be put in hand. Further donations should be sent to H.R.H. Prince Arthur of Connaught at 42 Upper Grosvenor Street, W.1.

IN *School Hygiene* (vol. xi., No. 1, February) Dr. A. A. Mumford puts forward an interesting scheme for the investigation and standardisation of the physical efficiency of children which is characterised by the breadth of view we should expect from the author of the "History of the Manchester Grammar School." Grading his subjects in six age-groups from two to eighteen, he indicates the materialistic tests which are appropriate. A boy of about thirteen, for example, should be able to run 100 yards in 14 seconds; for the oldest boys Flack's manometer test of expiratory force is of value. But realising, as medicine has come to realise more and more in recent years, the influence of the mind on the body, he emphasises the necessity of studying the emotional incentives to be found in the imagination, and would have the school medical officer pay attention to sulkiness as much as to adenoids. In the discussion of the paper Dr. Lempriere, of Haileybury, describes the quick, practical utility of height-weight ratios as indices of physical progress. Athletes are taller and heavier than the average, "crocks" shorter and lighter; it is, perhaps, characteristic that nothing is said about the physical qualities of the scholars and dunces.

Societies and Academies.

LONDON.

Royal Society, February 19.—Sir J. J. Thomson, president, in the chair.—**B. Moore** and **T. A. Webster**: Studies of photosynthesis in fresh-water algæ. (1) The fixation of both carbon and nitrogen from the atmosphere to form organic tissue by the green plant-cell. (2) Nutrition and growth produced by high gaseous dilutions of simple organic compounds, such as formaldehyde and methylic alcohol. (3) Nutrition and growth by means of high dilutions of carbon dioxide and oxides of nitrogen without access to atmosphere. The primeval living organism, like the inorganic colloidal systems which were its precursors, must have possessed the power of fixing carbon and nitrogen, and building these up into reduced organic compounds with uptake of energy. The source of the energy was sunlight. This power is still possessed by the lowliest type of synthesising cell existing, namely, the unicellular alga. A synthesising cell must have existed prior to bacteria and other fungi, since these can exist only upon organic matter, and the primeval world before the advent of life could contain no organic matter. Their specific reactions show that even the ultra-microscopic filter-passing organisms are highly organised products on the path from the inorganic towards life, and hence it follows that there is a long intermediate range of evolution. The first synthesising system acting upon light was thus probably an inorganic colloidal system in solution, capable of adsorbing the simple organic substances which it synthesised. It is therefore futile to search for the origin of life at the level of bacteria and torulæ. As complexity increased with progressive evolution, more and more rapid transformers for the capture of the energy of sunlight came into existence. Such transformers are found in the green cell for fixation of both carbon and nitrogen. The earlier transformers in the inorganic colloidal systems can only utilise light of short wave-lengths; the later transformers in the living cells are adapted to utilise longer wave-lengths; and the very short wave-lengths, which are lethal, are cut off by their colour-screens of chlorophyll, etc.—**W. M. Bayliss**: The properties of colloidal systems. iv.: Reversible gelation in living protoplasm. With intense dark-ground illumination it is possible to see that the apparently clear pseudopodia of Amœba are filled with numerous very minute particles in Brownian movement, thus affording further evidence of the liquid, hydrosol nature of simple protoplasm. By electrical stimulation this sol can be reversibly changed into the gel state, evidenced by the sudden cessation of the Brownian movement.—**F. J. Wyeth**: The development of the auditory apparatus in *Sphenodon punctatus*. This memoir contains a detailed and fully illustrated account of the development of the auditory apparatus and associated structures in the New Zealand Tuatara. As this important type is on the verge of extinction, it was thought desirable to treat the subject fully, although, as might be expected, the developmental history agrees closely with that found in other reptiles. The work was carried out chiefly by means of wax-plate reconstruction models. The third and fourth visceral clefts are closed by a backwardly growing operculum, but separate dorsal and ventral openings of the clefts were not observed. The existence of two pairs of head-cavities was confirmed, those of each pair communicating with each other by transverse canals. The vascular system was found to exhibit a number of primitive features. The region investigated includes cranial nerves vi.-xii., the development of which was worked out in detail. The general development of the internal ear and auditory nerve is thoroughly normal. The development of the cristæ and maculæ acusticæ from the primitive neuroepithelium is given in detail. A well-marked macula neglecta is found. As regards the much-debated question of the origin of the columellar apparatus, evidence is brought forward in support of the contention that this is essentially a derivative of the hyoid arch, and it is maintained that the auditory capsule contributes at most a portion of the foot-plate of the stapes.

Linnean Society, February 19.—Dr. A. Smith Woodward, president, in the chair.—Major H. C. **Gunton**: Entomological-meteorological records of ecological facts in the life of British Lepidoptera. The author believed that interesting facts would be obtained by recording and plotting the results of observations made by a number of entomologists in various localities. The scheme exhibited was derived from his notes from February to December, 1919, within a radius of four miles from Gerrard's Cross, Bucks, which includes oak and beech woods, heath, marsh, and cultivated land. Special signs are used to denote the occurrence of species of macro-Lepidoptera on sallow-bloom in the spring, ivy in the autumn, sugar, and light. Thirty-five species of butterflies and two hundred and forty species of moths are thus tabulated and correlated with meteorological data. The diagram places many facts before the eye, as the long continuance of certain species, the presence of more than one brood, and the like. Sugar scarcely appeals when honey-dew is abundant, and artificial light is ineffective during bright moonlight. Other problems, as of immigration, still await solution.

PARIS.

Academy of Sciences, February 9.—M. Henri Deslandres in the chair.—P. A. **Dangeard**: The plastidome, vacuome, and spherome in *Selaginella Kraussiana*.—G. **Charpy**: The minute fissures in steel ingots. The mode of formation and method of detection of minute cavities in steel ingots are described, together with an account of their alteration during rolling and forging.—M. Leclerc du Sablon was elected a correspondant for the section of botany in succession to the late M. Farlow, and M. Luglon correspondant for the section of mineralogy in succession to M. Walcott, elected foreign associate.—C. **Rabut**: The reduction of contact transformations.—R. **Birkeland**: A reduction of Abelian integrals.—J. **Bourquart**: The Quaternary glaciation of Central Albania.—L. and E. **Bloch**: Some new spark spectra in the extreme ultra-violet. Measurements for wave-lengths between 1855 and 1500 A.U. are given for the ultra-violet spectra of cadmium, bismuth, nickel, and silver.—J. A. **Le Bel**: New observations on catathermic phenomena.—D. **Gauthier**: The synthesis of α-ketonic tertiary alcohols. A correction relating to the constitution of a body previously described.—J. **Guyot** and L. J. **Simon**: The action of water on methyl chlorosulphonate.—A. **Mailhe** and F. **de Godon**: The catalytic formation of ether oxides. Calcined alum is an excellent reagent for the conversion of ethyl alcohol into ether, with a yield of 71 per cent. This reaction has been extended to propyl alcohol (yield of ether 54 per cent.), isopropyl alcohol (yield 10 per cent.), isoamyl alcohol (yield 28 per cent.), and mixtures of alcohols. In the last case mixed ethers can be prepared.—P. **Bertrand**: The normal succession of the coal flora in the Gard coal basin.—L. **Besson**: Extraordinary haloes.—A. **Loubière**: The fungi of Brie cheese.—E. F. **Galiano**: The histology of the branchial hearts of *Sepia officinalis* and their appendices.—V. **Galippe**: Researches on the evolution of the protoplasm of certain plant-cells by the method of culture.—G. **Bertrand** and M. **Brocq-Rousseu**: The destruction of rats by chloropicrin. Both the rat and the rat-flea are readily destroyed by the vapour of chloropicrin, and, as this substance is without action upon cloth materials and dyes, it can be utilised for the destruction of rats in ships.

Diary of Societies.

THURSDAY, MARCH 4.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lt.-Col. E. Gold: The Upper Air: (i) Modern Methods of Investigation, and their Application in the War.

ROYAL SOCIETY, at 4.30.—Dr. F. F. Blackman: The Protoplasmic Factor in Photosynthesis.—G. E. Briggs: The Beginning of Photosynthesis in the Green Leaf.—Prof. B. Moore, E. Whitley, and T. A. Webster: Sunlight and the Life of the Sea.

LINNEAN SOCIETY, at 5.—Dr. A. B. Rendle, E. G. Baker, and S. L. Moore: A Contribution to the Flora of New Caledonia based upon the Collections of R. H. Compton in 1914.

ROYAL COLLEGE OF PHYSICIANS, at 5.—Dr. A. Castellani: The Higher Fungi in relation to Human Pathology (Milroy Lecture).

ROYAL INSTITUTE OF PUBLIC HEALTH, at 5.—Dr. T. G. Maitland: Hospital Treatment of Pulmonary Tuberculosis.

ROYAL SOCIETY OF MEDICINE, at 5.30.—Dr. W. Edgecomb: Visceral Fibrositis.—Discussion on paper by Dr. Ferreyrolle: Immunity and Mineral Water Treatment.

CHEMICAL SOCIETY, at 8.—E. H. Rennie, W. T. Cooke, and H. H. Finlayson: An Investigation of the Resin from Species of Xanthorrhœa Not Previously Examined.—L. S. Bagster: The Reaction between Nitric [illegible] and Copper.—M. Chikashige:

its Allied Arts.—J. N. Mukherjee: Coagulation of Metal Sulphide Sols, Part II. Influence of Temperature on the Rate of Coagulation of Arsenious Sulphide Hydrosols.
ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section), at 8.—G. Ley: Utero-Placental Apoplexy (Accidental Hæmorrhage). An Analysis of Fifty Cases.

FRIDAY, MARCH 5.

ROYAL ASTRONOMICAL SOCIETY, at 5.—(A Geophysical Discussion.) *J. de Graaf Hunter and Others: The Earth's Axes and Figure.*
CONCRETE INSTITUTE (at 296 Vauxhall Bridge Road), at 6.—*E. S. Andrews: Some Properties of Steel.*
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—Adjourned Discussion on *Recent Advances in Utilisation of Water Power. E. M. Bergstrom.*
INSTITUTION OF ELECTRICAL ENGINEERS (Students' Meeting) (at City and Guilds (Engineering) College), at 7.—Roger T. Smith: Presidential Address.
TECHNICAL INSPECTION ASSOCIATION (at the Royal Society of Arts), at 7.30.—W. L. Baillie: Sampling—Some Problems and Fallacies.
JUNIOR INSTITUTION OF ENGINEERS (at 39 Victoria Street), at 7.30.—F. H. Rolt: Notes on Gauge Testing and Measuring Appliances.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Hon. J. W. Fortescue: Military History.

SATURDAY, MARCH 6.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir J. J. Thomson: Positive Rays.

MONDAY, MARCH 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir John Cadman: Modern Development of the Miner's Safety Lamp.
ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5.
BIOCHEMICAL SOCIETY (Annual General Meeting) (at Institute of Physiology, University College), at 5.30.—S. S. Zilva: The Fat-Soluble Accessory Factor in Cabbage and Carrots.—A. Harden and S. S. Zilva: The Antiscorbutic Requirements of the Monkey.—A. Harden and S. S. Zilva: Dietetic Experiments with Frogs.—O. Rosenheim and J. C. Drummond: The Association of Fat-Soluble A with Lipochrome Pigments.—F. R. Henley: Bacterial Process for the Manufacture of Acetone.
SURVEYORS' INSTITUTION (Junior Meeting), at 7.
ARISTOTELIAN SOCIETY (at 74 Grosvenor Street), at 8.—M. Ginsberg: Is there a General Will?
MEDICAL SOCIETY OF LONDON, at 8.30.—Dr. W. H. Willcox: Heat Hyperpyrexia: The Clinical Aspect.—Dr. L. E. Hill: The Physiological Aspect.

TUESDAY, MARCH 9.

ROYAL HORTICULTURAL SOCIETY, at 3.—J. Hudson: Fruits which can be Grown under Glass without Fire Heat.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Keith: British Ethnology—The Invaders of England.
ROYAL COLLEGE OF PHYSICIANS, at 5.—Dr. J. L. Birley: The Principles of Medical Science as applied to Military Aviation (Goulstonian Lecture).
INSTITUTION OF CIVIL ENGINEERS, at 5.30.—Maj.-Gen. Sir Gerard M. Heath: Royal Engineer Work in the Great War.
BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6.—D. J. Collar: A Statistical Survey of Arithmetical Ability.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—G. I. Higson: Photomicrography in Photographic Research.—K. Hickman: (1) A New Washing Device and Plate Rocker; (2) Dark-room Illumination by means of Lamps in Liquid Cells.
QUEKETT MICROSCOPICAL CLUB, at 7.30.

WEDNESDAY, MARCH 10.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir John Cadman: Petroleum and the War.
ROYAL SOCIETY OF ARTS, at 4.30.—H. M. Thornton: Gas in Relation to Industrial Production and National Economy.
GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Prof. A. H. Cox and A. K. Wells: The Lower Palæozoic Rocks of the Arthog-Dolgelley District.

THURSDAY, MARCH 11.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lt.-Col. E. Gold: The Upper Air: (ii) Results and their Interpretation.
INSTITUTE OF METALS (at Institution of Mechanical Engineers) (Annual General Meeting), at 4.—Eng. Vice-Admiral Sir George Goodwin: Inaugural Address.
ROYAL SOCIETY, at 4.30.—*Probable Papers*—W. G. Duffield, T. H. Burnham, and A. A. Davis: The Pressure upon the Poles of Metallic Arcs, including Alloys and Composite Arcs.—J. H. Vincent: Further Experiments on the Variation of Wave-length of the Oscillations Generated by an Ionic Valve Due to Changes in Filament Current.—H. A. Daynes: (1) The Theory of the Katharometer; (2) The Process of Diffusion through a Rubber Membrane.
ROYAL COLLEGE OF PHYSICIANS, at 5.—Dr. J. L. Birley: The Principles of Medical Science as applied to Military Aviation (Goulstonian Lecture).
ROYAL SOCIETY OF MEDICINE (Occasional Lecture), at 5.—Sir Jagadis Bose: Plant and Animal Response (with Demonstrations of Growth by the Magnetic Crescograph).
CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Miss M. Jane Reaney: The Educational Needs of Adolescence.
INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—W. H. Patchell: Operating a By-Product Producer-Gas Plant for Power and Heating.—S. H. Fowles: Production of Power from Blast-furnace Gas.
OIL AND COLOUR CHEMISTS' ASSOCIATION (at 2 Furnival Street), at 7.—J. B. Shaw: Various Points in the Manufacture of Lake and Pigment Colours.
OPTICAL SOCIETY, at 7.30.
INSTITUTION OF AUTOMOBILE ENGINEERS (Graduate Section), at 8.—C. A. Chappell: Magnetos.
INSTITUTE OF METALS (at Institution of Mechanical Engineers) (Annual General Meeting), at 8.—Dr. G. D. Bengough, R. M. Jones, and Ruth Pirret: Fifth Report to the Corrosion Research Committee.—R. Seligman and P. Williams: The Action on Aluminium of Hard Industrial Waters.
ROYAL SOCIETY OF MEDICINE (Neurology Section), at 8.30.—Prof. J. S. B. Stopford: Results of End-to-end Suture of Peripheral N[illegible]

FRIDAY, MARCH 12.

INSTITUTE OF METALS (at Institution of Mechanical Engineers) (Annual General Meeting), at 10.30.—J. Neil MacLean: The Art of Casting in High Tensil Brass.—H. Moore and S. Beckinsale: The Removal of Internal Stress in 70: 30 Brass by Low-temperature Annealing.—Dr. W. Rosenhain, J. L. Haughton, and Kathleen Bingham: Zinc Alloy with Aluminium and Copper.—Dr. W. Rosenhain: A Model for Representing the Constitution of Ternary Alloys.—A. C. Vivian: Tin-Phosphorus Alloys.—W. C. Hothersall and E. L. Rhead: Some Notes on the Effect of Hydrogen on Copper.
INSTITUTE OF METALS (at Institution of Mechanical Engineers) (Annual General Meeting), at 2.30.—*W. E. Alkins: The Effect of Progressive Drawing upon some Physical Properties of Commercially Pure Copper.—F. Johnson: The Influence of Cold Rolling on the Physical Properties of Copper.—J. L. Haughton: The Study of Thermal Electro-motive Force as an Aid to the Investigation of the Constitution of Alloy Systems.—H. H. Hayes: The Polishing and Etching of Zinc for Micro-examination.—W. E. Hughes: Idiomorphic Crystals of Electro-deposited Copper.*
ROYAL ASTRONOMICAL SOCIETY, at 5.
PHYSICAL SOCIETY OF LONDON, at 5.—F. W. Newman: Absorption of Gases in the Electric Discharge Tube.—F. S. G. Thomas: A New Directional Hot Wire Anemometer.—Dr. Hans Pettersson: Exhibit of a New Micro balance.
MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—W. W. Rouse Ball: String Figures.

SATURDAY, MARCH 13.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir J. J. Thomson: Positive Rays.

THURSDAY, MARCH 11, 1920.

The State and the National Museums.

WHILE reconstruction in almost every direction is in the air, there is a very real danger that the needs of our national museums may escape notice. The time is, indeed, more than ripe for the State to consider with all due care whether their value to the community might not be vastly increased were there some system of co-ordination between them, the connecting links being of sufficient flexibility to allow each of them to perform its proper work without the irksome trammels that accompany undue centralisation. In the course of two reports issued by the late Ministry of Reconstruction, certain suggestions are made for achieving this end; to them we shall refer later. The proposal which we put forward is not very different, but we consider it to be a more complete solution. To apprehend more correctly the nature of the problem, it will be necessary first to set out briefly the origin and the present position of the principal national museums.

Perhaps without exception the museums came into being, not as parts of some wide and comprehensive scheme, but casually and at haphazard because some particular contingency arose and had to be met. The oldest and most famous of them—the British Museum—was founded in 1753 for the purpose of housing and conserving the valuable collections which had been bequeathed to the nation by Sir Hans Sloane, a great antiquary and collector in his day. In the following century the growth of the collections was so great, fed as they were by donations, bequests, and parliamentary grants, and, as regards the library, by the operation of the Copyright Act, that it became necessary in the early 'eighties to transfer the natural history collections to the new buildings at South Kensington which had been erected for their reception. But the rate of growth of the collections tended ever to increase, and additional accommodation was soon urgently needed at both branches of the museum. It was only just before the outbreak of war that a new wing was opened at Bloomsbury by the King and Queen, while the plans which had been prepared for relieving the congestion at South Kensington had, owing to the war, necessarily to be held in abeyance, and it is uncertain when it will be possible to proceed with them.

The original Act of Parliament constituting the museum provided for its governance by a body of trustees; this arrangement still remains, and no exception could be taken to it were it not for the fact that election to the standing committee of the British Museum has come to be regarded as a distinction to be awarded on quite irrelevant grounds, and that, owing in the past to the little attention given to science in the public schools, this process has not in general led to the selection of trustees most suitable for the Natural History Museum. Despite the actual physical distance between the two branches of the British Museum, and the great difference in the character of the work carried on at the two institutions, they are still officially regarded as one museum; and the Natural History Museum is subordinated to the parent establishment, the official title of its director being Director of the Natural History Departments. There can, unfortunately, be little question that the development of the Natural History Museum has been grievously hampered by the persistent attempt made to fit it to a system devised for the older building, and especially for the great library, which has, in fact, always tended to overshadow the rest of the museum.

The institution which was at one time known as the South Kensington Museum originated in the collections which were purchased at the Exhibition of 1851 on account of the excellence of their art and workmanship. Half a century later the need for expansion had become acute, and plans for new buildings were put in hand, but in the reorganisation of this museum wiser counsels prevailed, and the Science Museum was created a separate institution, quite independent of the Art Museum, afterwards known as the Victoria and Albert Museum. The title of the former museum cannot be considered altogether happy, since it is concerned, not with science in general, but chiefly with engineering and applied mechanics. Both museums are administered by the Board of Education.

The Museum of Practical Geology was a necessary concomitant of the Geological Survey, which was instituted in 1832. Plans had been prepared for bringing this museum and the offices of the Survey to a new building to be erected near the Natural History Museum at South Kensington, but the war intervened, and many years are likely to elapse before they reach maturity. Up to a few months ago the Survey was attached to the Science Museum under the administration of the Board of Education, but it has now been transferred to the Department of Scientific and Industrial Research, the creation of which is one of the few beneficent results of the war.

The London Museum, now located at Lancaster

House, was instituted for the conservation of the antiquities of London. The Wallace Collection, bequeathed to the nation in 1897, is contained in Hertford House, which was acquired by the Government for the purpose. Both the last-named museums are under independent bodies of trustees. The Imperial Institute contains large collections of the economic products of the Empire, and a scientific and technical staff has been provided for their conservation and study; it is managed by the Secretary of State for the Colonies, assisted by an executive committee. Towards the close of the war the Imperial War Museum was founded for the preservation and custody of objects and records connected with the war. Besides the museums, there are the various picture galleries in London, all under independent bodies of trustees, and outside London there are important national museums at Edinburgh, Cardiff, and Dublin, all under their own authorities.

Owing to the overlapping of the scope of several of these institutions, there often arises duplication of work and competition for the acquisition of specimens. Thus similar ground is covered by certain sections of the British Museum and the Victoria and Albert Museum as regards art; by the Natural History Museum, the Geological Museum, and the Imperial Institute as regards minerals and rocks; by the Natural History Museum and Kew Gardens as regards the systematic study of plants. There is further overlapping in the range covered by the associated libraries—to some extent that is both desirable and inevitable—but at the same time no attempt is made to ensure that a copy of every important book or periodical is accessible in London.

The lack of co-ordination between the various museums was noticed by the Sub-Committee, under the chairmanship of Lord Haldane, which was appointed by the Reconstruction Committee in July, 1917, to investigate the machinery of Government, and confirmed in its appointment when the Ministry of Reconstruction began its brief existence. In its report published in 1918 (Cd. 9230) the following important paragraph occurs:—

"As regards the other national museums [*i.e.* other than the Geological Museum, the suggested transference of which to the Department of Scientific and Industrial Research was approved] . . . , we think that the responsible authorities might consider with advantage the possibility of entering into regular arrangements, by means of a body representative of each of the museums, and established for the purpose, whereby the spheres of the respective museums should be arranged with a view to the avoidance of competition for objects, and to the development of each museum to the full as a centre of education and research. From the latter point of view it would no doubt be desirable to secure that the Board of Education, and the general organisation for research and information, . . . should be associated with any movement in this direction."

In this connection we may refer also to the third interim report by the Adult Education Committee, which was also appointed by the Ministry of Reconstruction, in its report on libraries and museums (Cd. 9237, 1919), in which it is urged that "the powers and duties of the Local Government Board regarding [the local] public libraries and museums should be transferred forthwith to the Board of Education." Those interested in such institutions promptly took steps to register their strong disapproval of the course proposed; with that dissent we are in full accord. It must be remembered that it is the business of the Board of Education to allocate parliamentary grants to schools and other teaching institutions, and to see that the range of the curriculum of the studies at them adheres to the official regulations, and not to take part in the actual practice of education. A department of which the vision is restricted by the blinkers of sub-heads and schedules is not often able to take a broad view on questions of learning and research.

In our opinion the best solution of the difficulty would be to expand the present Department of Scientific and Industrial Research into a Ministry of Learning and Research, and to bring under it the national museums and picture galleries, as well as the national institutions engaged in research. To ensure proper co-ordination and continuity of policy, the administration of the proposed Ministry should be entrusted to a board of trustees, comprising representatives of the standing committees appointed to control each of the constituent establishments.

We recognise the complexity of the question, and our readers must not assume that we consider the solution which we offer to be beyond criticism and discussion. In the House of Lords on March 3 Lord Sudeley suggested that the Government should appoint a committee on museums and galleries "to consider and recommend how these institutions can be further adapted to public needs, and especially be made throughout the country of far greater use for public benefit and instruction." His lordship made it clear, in the course of the speech with which he intro-

duced the motion, that he had in mind the ordinary member of the public, and particularly the child in the elementary school, and appeared to be under the impression that the expert was already sufficiently well cared for. An instructive feature of the debate is the almost entire absence of any reference to science in general, or to the Natural History Museum in particular. Another revealing point is suggested by a passage in Lord Crawford's reply for the Government, in which, in reference to Lord Bryce's proposal that a central scientific department of the Government should be set up, he said: "Among the purposes for which the Scientific and Industrial Research Department was set up . . . is actually that of acting as a central advisory body on any scientific question in relation to any Government Department"; for, apropos of this statement, we must observe that, whereas every administrative Department is represented by at least one assessor to the Advisory Council, that Department appears to be unaware of the existence of the Natural History Museum. Lord Sudeley's motion was eventually by leave withdrawn; nevertheless, we hope that the matter will not be allowed to rest there. We think, indeed, the question of sufficient importance for the consideration of a Royal Commission, the terms of reference of which should include the system of remunerating the specialist, who at present enjoys a much lower scale of salary than the administrator of corresponding standing, and we strongly urge the Government to appoint one with the least possible delay.

Mathematical Cosmogony.

Problems of Cosmogony and Stellar Dynamics. By J. H. Jeans. Being an essay to which the Adams prize of the University of Cambridge for the year 1917 was adjudged. Pp. viii+293+v plates. (Cambridge: At the University Press, 1919.) Price 21*s.* net.

IN a well-developed science two branches are broadly to be distinguished. In the one, an existing state of things is investigated. The subject of research is events immediately connected, forms, functions, and the laws which govern them. The other branch generally marks a later stage, and, basing itself on the results of the first, seeks to reconstruct from the present as complete a picture as possible of the past and even of the future. As in the conception which underlies the theory of relativity, the present, which is the limited subject of experience, is merely a section in time from which a higher manifold is to be deduced. When the subject-matter is biological, the outcome is a theory of evolution. When it coincides with the domain of astronomy, the result is more specifically recognised as a scheme of cosmogony.

There are at least three methods by which attempts have been made to formulate such a scheme. The first, and most trivial, is to seize on some remarkable phenomenon, like Saturn's rings or a spiral nebula, and to see in it a clue which can be followed up more or less plausibly with the help of an exuberant and unfettered imagination. Progress on that line is naturally as limited as it is precarious. The second method is illustrated in its highest form by the work of Sir W. Herschel. It is the way of comparison and classification. The Draper classification of stellar spectra by Pickering is an apt modern example. Without preconception, except such as readily vanished in the light of fuller experience, almost all the stars fell into an ordered sequence, which became more complete and continuous as the material accumulated. To connect the ascertained sequence with a time scale was natural. But the problem has not proved quite so simple as at one time it appeared. In general, when the process is exceedingly slow and the section of experience correspondingly thin, the very direction of the scale is ambiguous, and the method requires to be supplemented by some additional principle. A third method remains. This consists in the study of models having a definite specification as nearly as possible in accordance with cosmic examples, but always within the power of analysis to discuss. The behaviour and development of such a model are traced to their logical consequences with full mathematical rigour, and only after this has been done is an attempt made to find their counterparts in the actual universe. This is the profoundly difficult but promising method adopted by Sir George Darwin, by Poincaré, and by Mr. Jeans in the work under notice.

It is curious how great are the difficulties which surround problems capable of the simplest statement. Three balls are thrown in any given way in empty space. All the intractable difficulties of the problem of three bodies are involved in discussing the subsequent motion under their mutual attractions. Or again, to take the fundamental problem of the present subject, a mass of liquid is stirred into rotation and left to find its shape under its own attraction. What figure will it assume when isolated in space? The following quotation from Thomson and Tait may be worth recalling:—

"During the fifteen years which have passed since the publication of our first edition, we have never abandoned the problem of the equilibrium

of a finite mass of rotating incompressible fluid. Year after year, questions of the multiplicity of possible figures of equilibrium have been almost incessantly before us, and yet it is only now, under the compulsion of finishing this second edition of the second part of our first volume, with hope for a second volume abandoned, that we have succeeded in finding anything approaching to full light on the subject."

The full light, it must be admitted, was rather dim, especially as such results as had been obtained were published without proof. But it sufficed to lead Poincaré to write a celebrated memoir on the subject, and this, with the contemporary and independent work of Liapounoff, has been the germ of all subsequent advance.

The first step had been taken by Maclaurin, who showed that the spheroid was a possible figure of equilibrium. The second solution was found by Jacobi in the form of an ellipsoid with three unequal axes. In the cosmical problem the whole mass and the moment of momentum are given constants; the angular velocity increases as the state of contraction advances, but so slowly that the development follows a succession of equilibrium figures. Thus a body traces out the series of Maclaurin to the point where it meets the series of Jacobi, and where secular stability is interchanged between the two series. Proceeding along the second series, it comes to the first point, discovered by Poincaré, where another possible series intersects. Here the Jacobian series becomes unstable, and it was a question whether the stability passed over to the series of deformations, or whether it disappeared completely at this point, in which case the figures of statical equilibrium would come to an abrupt end and be followed by a rapid change under dynamical conditions.

It was not in Poincaré's nature to embark on the complicated arithmetic needed to solve the question; but this part of the work was supplied by Liapounoff and by Darwin, who arrived at opposite conclusions, the latter maintaining that the deformed figure was stable. These three writers all used Lamé's functions in the discussion, and carried the development to the second order. One cannot help feeling that, in spite of his courage, Darwin was in this instance trying to stretch a bow a little beyond his strength. At any rate, the important problem remained undecided for some years. Mr. Jeans began his attack on it by forging a lighter and handier weapon, described in chap. iv. of the present work, on the gravitational potential of a distorted ellipsoid. His next step was to show that no conclusion could legitimately be drawn from a development to the second order; and finally, on proceeding to the third order, he proved definitely that the figure at the point where the series bifurcate is unstable, thus closing a dispute remarkable in the case of a definite issue between authorities so eminently qualified. After this signal achievement as regards the incompressible fluid mass Mr. Jeans extended his researches to rotating masses of compressible and heterogeneous fluid, hitherto an almost untouched field. In following out the development of such bodies as exemplified in different selected models, he has shown always the same originality, resource and power.

In the present essay, which will be warmly welcomed, Mr. Jeans brings together these and other related researches in a connected form, but at the same time he adds so much of the work of his predecessors that his own is seen in its proper setting, and the whole book forms a fairly complete treatise on the subject. The earlier chapters provide that firm mathematical foundation to which the author has contributed so largely, while the later chapters deal in turn with the different classes of celestial objects to which the theory can be applied—rotating nebulæ, star clusters, binary and multiple stars. The origin of the solar system, the very point at which speculations of this order began, remains apparently more elusive than ever. The later part of the book can be read with profit by many to whom the power of appreciating the earlier mathematical chapters has been denied. It will be found exceedingly interesting, and will repay the most careful attention. Here the speculative element necessarily enters, and the permanent value which belongs to the abstract problems definitely solved cannot be assumed. But ingenuity and a wide knowledge are always in evidence, and the essay should have an immediate value equally in limiting the area of profitable speculation and in suggesting lines which can be controlled by observation.

Of the technical excellence of the production, which is always a point of real importance in a mathematical text, it is unnecessary to say more than that it is worthy of the Cambridge University Press. There is an obvious, and therefore harmless, misprint in equation (72) (p. 38), and "Meyers" (p. 248) for "Myers" betrays an unverified quotation. On p. 2, "parallaxes are less" should read "greater." But these are trifling exceptions to the rule of accuracy. Beautiful pictures like the photographs of selected nebulæ included by Mr. Jeans are an unusual feature in a mathematical work. They have been supplied from the Mount Wilson Observatory, and are masterpieces of their kind.

H. C. P.

Tropical Medicine.

Fevers in the Tropics. By Sir Leonard Rogers. Third edition. Pp. xii + 404 + 9 plates. (Oxford Medical Publications.) (London: Henry Frowde and Hodder and Stoughton, 1919.) Price 30*s.* net.

THIS, the third edition of Sir Leonard Rogers's well-known work, has, in our opinion, been improved by the pruning process to which it has been subjected, but it may be doubted whether the process has been sufficiently drastic, and personally we should breathe a sigh of relief if the "Burdwan fever" and some other hardy perennials were finally laid to rest. The distinguishing character of the author's method is the great importance which he attaches to the study of temperature charts and to leucocyte counts as means of diagnosis, with the result that, perhaps unwittingly, he scarcely emphasises sufficiently that in diseases of a parasitic nature these can be only of secondary importance. Thus "a great leucopenia" may be "greatly in favour of kala-azar," but a diagnosis can be made with certainty only in one way, viz. by finding the parasites; and as it is not stated whether this has been done in the many examples, accompanied by charts, given of "this disease," we are uncertain whether they really are "this disease," or examples of another disease, possibly the 43 per cent. of "kala-azar" cases in which parasites are *not* found, and which, for all we know to the contrary, may also show "a great leucopenia."

The author's exposition of these indirect methods of diagnosis consumes, we think, too much space, so that pathological histology, which should form our only certain basis for the interpretation of symptoms, receives rather scant attention. Thus nothing is said of the changes in American trypanosomiasis, and those of malaria and blackwater fever, for example, are very incompletely described.

Again, although twenty-one pages are allotted to a discussion of pre-suppurative hepatitis, we ourselves do not know what a liver in this condition would look like, as no post-mortem descriptions are given.

Under blackwater fever it is stated that "the parasite most commonly met with is the malignant tertian, the other forms being rare." If the other forms are rare, as in a malaria district like West Africa, or the Duars in India, this is only what one would expect; consequently, the statement has little significance; but if we are considering a district like the Panama Canal, where the simple tertian parasite forms about 26 per cent. of the malaria cases, then this statement is not true, for we find that about the same percentage—viz. 24 per cent.—of the blackwater cases show simple tertian parasites, and on the Madera River, Brazil, where simple tertian forms about 30 per cent. of the malaria cases, the percentage for the blackwater cases is 42 per cent.

On p. 66 we find a common error repeated—viz. that tsetse-flies in the resting position can be distinguished from all other flies by the wings "closed . . . like the blades of a pair of scissors"; and on p. 86, probably through a lapse of memory, it is said that tartar emetic is specific for American trypanosomiasis; unfortunately, it appears to have no action on it. Misprints are rather numerous: *Crintridia* for *Crithidia, Triomata* for *Triatoma, lenticularis* for *lectularius, sodia* for *sordida, tropical* for *tropica, galinarum* for *gallinarum*, etc.

Readers who do not already know the work will find something different from the ordinary text-book, but we think they would be glad if the author's well-known clinical enthusiasm could express itself more tersely and—dare we say it?—more critically. J. W. W. S.

Practical Chemistry.

(1) *A Text-book of Quantitative Chemical Analysis.* By Dr. A. C. Cumming and Dr. S. A. Kay. Third edition. Pp. xv + 416. (London: Gurney and Jackson; Edinburgh: Oliver and Boyd, 1919.) Price 12*s.* 6*d.* net.

(2) *A Course of Practical Chemistry for Agricultural Students.* Vol. ii. Part i. By H. A. D. Neville and L. F. Newman. Pp. 122. (Cambridge: At the University Press, 1919.) Price 5*s.* net.

(3) *Chemical Calculation Tables: For Laboratory Use.* By Prof. H. L. Wells. Second edition, revised. Pp. v + 43. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1919.) Price 6*s.* 6*d.* net.

THERE is always a tendency among students of analytical chemistry to value their work by its quantity and the nearness of their results to what is assumed to be correct, and in this they are often encouraged by those who have the direction of their studies. They do as they are told in their text-book—weigh out so much, dissolve in 200 c.c. of water, add 20 c.c. of a stock reagent, heat to boiling, wash three times by decantation, and so on; and in the end, though they get an excellent result, they have learned not so much chemistry as if they had made an apple dumpling by intelligently following the instructions of a cookery book.

There is only one way to learn practical chemistry, and that is to study the work as well as do it. A student should not pass from an estimation until he knows definitely the reason for every step in the process, how it can be proved to be complete, and why the operation is done in the way it is rather than in an alternative way. He should make a rule of proving that his product is what he means it to be, and that it is pure. In short, he should make a thorough study of every piece of work. He may get fewer results, but he will have learned more chemistry, and he will have gained the only true confidence, namely, that founded on knowledge.

We deprecate, as a rule, general instructions, such as that every precipitate should be ignited two or more times until it ceases to change in weight. Some products need it, some do not. The point for consideration is, What is present that it is desired to get rid of by the ignition, and what conditions are necessary to eliminate it with certainty? Unless the student knows this and concentrates his attention upon it, he is working by mere rule of thumb. As to purity of product, we have known a conscientious and careful worker to get a good result for one of the minor constituents of an ore, but when it was suggested that he should examine the product that he had weighed, he did so, and found that it did not contain even a trace of the compound of which he thought it consisted.

(1) The manual by Drs. Cumming and Kay is an excellent text-book for students. It includes a full course of mineral analysis, finishing with instructions for the analysis of several alloys and ores, gas analysis, water analysis, organic analysis, the determination of molecular weights, and various desirable tables. There are many helpful and practical hints, though we think that some parts might profitably be a little expanded on the lines indicated above. The method of igniting ferric hydrate without separation from the filter paper containing it is, of course, not original with the authors, but we think that it will be found generally to lead to a notably short weight, because the reoxidation of the reduction products is very uncertain.

(2) This "Part" of Messrs. Neville and Newman's course deals only with exercises on "pure organic chemistry." It covers the examination of many classes of organic bodies, finishing with proteins and enzyme action. It is a well-arranged course for students of agriculture. Like so many others who refer to the production of acetaldehyde for detection purposes, the authors describe its odour as characteristically fruity.

(3) The "Chemical Calculation Tables" include a five-figure table of logarithms with a double thumb index that enables the user to turn immediately to any desired page either backwards or forwards. There are extensive tables of factors and weights, giving both the number and the logarithm, and tables referring to gas calculations and molecular weight determinations. It is exactly what one wants to facilitate calculations in the laboratory.

C. J.

Botanical Guides.

(1) *Applied Economic Botany: Based upon Actual Agricultural and Gardening Projects.* By Dr. M. T. Cook. (Farm Life Text Series.) Pp. xviii+261. (Philadelphia and London: J. B. Lippincott Co., 1919.) Price 7*s*. 6*d*. net.

(2) *Some Familiar Wild Flowers.* Photographed by A. E. Sulman. Pp. ii+65. (Sydney: Angus and Robertson, Ltd., n.d.) Price 1*s*. net.

(3) *Australian Wild Flowers.* Photographed by A. E. Sulman. Second Series. Pp. ii+61. (Sydney: Angus and Robertson, Ltd., n.d.) Price 1*s*. net.

(4) *A Popular Guide to the Wild Flowers of New South Wales.* By Florence Sulman. Vol. ii. Pp. xxxi+249+71 plates. (Sydney: Angus and Robertson, Ltd., 1914.) Price 6*s*. net.

(1) THE title of Dr. Cook's book is misleading; from the preface we learn that it is intended as a guide to experimental work in the study of plants, such as should be carried on in any high school, and as a preliminary work to the agricultural studies which are now recognised in many high schools. These objects would be served by a good general practical introduction to the study of plant life, and this, we gather, is what Dr. Cook is attempting. Part i., "Plant Life," occupies nearly three-fourths of the volume. Beginning with the seed and seedling, the form of the various plant organs and their uses to the plant are described in successive chapters, and exercises for practical work are suggested at the close of each chapter. A short chapter on the anatomy of the angiospermous plant follows, then a brief description of the chemical composition and a chapter on plant food and growth, and finally very short chapters on the Gymnosperms, ecological relations, forestry, plant-breeding, weeds, Pteridophytes, Bryophytes, Thallophytes, and Bacteria.

The remainder of the book, part ii., entitled "Important Families of Economic Plants," is an account of a number of plants of economic value arranged in their families, with a short and often very inadequate description of the characters of each family. The general effect is scrappy. There

are a large number of figures, many of which are good, but others are poor, as, for instance, some of those in the chapter on flower-types. A photograph of two ripe ears of Indian corn is described as the pistillate flower. The use of the terms "endogenous" and "exogenous" for the stem of the monocotyledon and dicotyledon respectively is not helpful; and to describe the flower as consisting of "leaves which have been greatly modified in shape and colour" may be misleading. Annual rings are invariably referred to as annular rings. The introduction contains excellent advice on methods of studying botany, but the book as a whole is disappointing.

(2) and (3) The two little books by Mrs. Annie Sulman form a series of very fair reproductions of photographs of some of the common Australian wild flowers, and each is very well worth the shilling. There is no letterpress apart from the short preface and index; the botanical and, where such exists, the popular names are given below each plate, and the colour of the flower is indicated. There is little attempt at arrangement; generally the species of the same genus are brought together, but members of the same family appear in different parts of the books. If the author would arrange the plants in some definite sequence and indicate in each case the family to which the plant belongs, she would add to the usefulness of these little volumes.

(4) Miss Sulman's "Popular Guide to the Wild Flowers of New South Wales" is complementary to the volume previously issued. It forms a very handy and well-arranged working flora descriptive of a large number of New South Wales flowering plants, illustrated by clear, well-drawn, and eminently helpful full-page illustrations. The arrangement is that of Bentham's "Flora Australiensis." There are a useful illustrated glossary, a list of books of reference, a key to the families, twenty-nine of which are included, and, at the end of the volume, a colour index, by which a clue may be obtained to the name of a flower. The descriptions of the plants are clearly written, and a great deal of information is given in a small space.

Our Bookshelf.

Agriculture and the Farming Business. By O. H. Benson and G. H. Betts. Pp. xvi+778. (London: Kegan Paul and Co., Ltd., n.d.) Price 10s. 6d. net.

MESSRS. BENSON AND BETTS have essayed an ambitious task; it is no less than to make their volume a clearing-house for the mass of valuable scientific information about agricultural problems now accumulated at experiment stations and colleges, but not always wanted by practical farmers. Although the book emanates from a London publisher, it is entirely written for the American farmer.

The scope of the book is unusually wide; it deals with office equipment, crops, animals, manures, soil fertility, implements, motor-cars, roads, education, recreation and health, and finally there is a miscellaneous chapter including such diverse subjects as the removal of stains, the quantity of seed to sow per acre, a planting table, etc. Full information about all these things could scarcely be expected, and yet a vast amount of material is collected. Unfortunately, it is of very unequal value; there are few tables of figures and practically no references; the student wishing to check the data cannot do so, and the farmer seeking information is not told where he can obtain it. Thus, under "The Origin of Wheat," the only information given is: "Just where wheat came from none can say. Some think it originated in the Valley of the Nile or the Euphrates, or possibly that it may have come from Sicily. Wherever it originated, it seems to have developed from one of the wild grasses. Certain scientists think it descended from the lily; others tell us that it is probably a descendant of the wild ammer."

This statement is not very satisfying. Like many others in the book, however, it might serve to whet the farmer's curiosity, and some good would then be served by references to trustworthy specialised books or bulletins. If a second edition is called for, the authors might well seriously consider these points.

Geography of Asia. By Joseph Martin. (Macmillan's Practical Modern Geographies.) Pp. viii+298. (London: Macmillan and Co., Ltd., 1919.) Price 5s.

THE tendency of school geography to embrace too much and so to fail in achievement has been avoided in this book, which is well proportioned and thoroughly geographical throughout. Mr. Martin has the courage to omit considerations of geological structure where it has no direct bearing on human activity. Physical explanations of climatic problems are generally omitted. The diagram of the planetary winds is an improvement on that produced in most text-books, but should have the polar high-pressure areas added. Asia is treated under the larger natural regions, but these are not allowed to obscure the political units which are an essential to a full understanding of world geography.

Each chapter is prefaced by some simple statistical matter on which is based a number of exercises designed in the main for oral answers. At the end of each chapter are a number of mapping exercises. The extent to which wide generalisations are admissible in school geography will always be a disputed point, but statements that certain climates are unhealthy to Europeans, if true, require explanation. Even a school geography should emphasise the part played by the mosquito.

More than fifty excellent black-and-white maps, most of which show relief, and as many finely reproduced illustrations add considerably to the value of the book. One or two small points might be corrected in the next edition. The number of emigrants entering Asiatic Russia was scarcely 250,000 a year immediately before the war. The figure given for Siberia on p. 264 is much too high. It would be more correct to say that the Kara Sea is navigable for two months than that it is ice-free for that period. The railways to Kuznetsk and Minusinsk should be noted. The use of a volume like this must result in raising the standard of geographical teaching, and, incidentally, in justifying full attention to the subject in the school curriculum.

Submarine Warfare of To-day. By Lieut. Charles W. Domville-Fife. (Science of To-day Series.) Pp. 304. (London: Seeley, Service, and Co., Ltd., 1920.) Price 7*s.* 6*d.* net.

THE Allied peoples, to whom the defeat of the German submarine campaign has meant so much, cannot fail to be interested in the means by which that defeat was consummated. Hitherto they have had to rely on scraps of information—perhaps true, perhaps not—whispered in the ear or appearing furtively in the Press. An urgent demand undoubtedly exists for a comprehensive statement of the case. Lieut. Domville-Fife has given us that—and more. His book is full of romance as well as of facts. The victory over the submarine was won, not by any sovereign remedy for their depredations, or by a single weapon invincible in attacking them, but by the cumulative effect of a multitude of devices, each itself imperfect, but employed systematically and in spite of numerous failures. To which must be added—and the author gives this its proper proportion by telling actual incidents in a fine literary style—the bravery and pertinacity of the men on the ships.

The only criticism which is permissible is that the book is somewhat lacking in detailed description of the instruments used—the directional hydrophone, for example. Possibly this omission is due to the continued maintenance of official secrecy in such matters. This probably also accounts for the lack of all reference to certain new devices which were used with considerable effect, or to the development of others which will in future render the action of the submarine increasingly difficult.

Hidden Treasure: The Story of a Chore Boy who Made the Old Farm Pay. By J. T. Simpson. Pp. 303. (Philadelphia and London: J. B. Lippincott Co., n.d.) Price 6*s.* net.

MR. SIMPSON has woven many of the features of modern farming into a story of an American college youth who went to a Pennsylvanian farm owned by a very conservative uncle just about to marry and set up housekeeping. The young man's suggestions for improvements are received with the usual incredulity, the uncle even declining to oil the wheels of the grindstone, because he has never done it before. But before the onslaught of the boy's "git up and git," and the insistence of the up-to-date wife, the uncle's prejudices slowly break down, and in one way and another the old run-out farm is gradually improved. New concrete buildings are put in, the tractor is introduced, the dairy herd is improved, and in course of time the farm becomes a completely modern establishment. The young man receives his reward; the local banker becomes interested in him, a desirable farm falls vacant, and in chap. xiii. (ominously enough) an eligible young woman turns up equipped with brown eyes and shy glances, and although the recorded conversations all relate to agricultural improvements, the perspicacious reader will have no difficulty in forecasting the end.

Flora of the Presidency of Madras. By J. S. Gamble. Part iii. *Leguminosae—Caesalpinioideae to Caprifoliaceae.* Pp. 391–577. (London: Adlard and Son, and West Newman, Ltd., 1919.) Price 10*s.* net.

THE third part of Mr. Gamble's handy little flora contains the remainder of the polypetalous dicotyledons. It includes the Cæsalpinia and Mimosa sections of Leguminosæ, containing many forest-trees and shrubs, and, among others, the important families Combretaceæ, Myrtaceæ, Melastomaceæ, and Cucurbitaceæ. As in previous parts, descriptions are given of families and genera, but the determination of the species depends on the keys in which the characters of the principal organs are fully contrasted. No typographic distinction is made between native and introduced genera, such as Parkinsonia (tropical American) and Eucalyptus (Australian); *E. globulus*, the blue gum, is largely grown in forests on the Nilgiris and other hills, and is frequently found self-sown. Another alien genus appears under the name Delonix, an unnecessary revival from Rafinesque; it includes the familiar "flamboyant" generally known as *Poinciana regia*. As with the previous part, the author has been restricted in the preparation of the work to material available in the great herbaria in this country, but for future parts the Indian collections will again be available.

La Théorie Atomique. Par Sir J. J. Thomson. Traduit de l'Anglais par le Prof. M. Charles Moureu. Nouveau tirage. Pp. vi + 57. (Paris: Gauthier-Villars et Cie, 1919.) Price 2.40 francs net.

THIS is a translation of the Romanes lecture of 1914, made during the war under the full inspiration of the Anglo-French comradeship in arms. The translator stipulated that the proceeds should go to the British Red Cross; Sir J. J. Thomson insisted that they should go to the French Red Cross; and, as neither would give way, they finally agreed that they should benefit the Belgian wounded. Prof. Moureu has given an excellent translation, which fully preserves the "*intérêt passionnant*" of the original lecture.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Gravitational Deflection of High-speed Particles.

MR. LEIGH PAGE has given a very simple method of treating the motion of high-speed particles in a gravitational field on Einstein's theory (NATURE, February 26, p. 692). In one respect his results differ from those which have been obtained by more laborious methods, and I think that some error must have crept in, either through a failure of his approximation or from some other cause. He finds that a particle travelling with the velocity of light would be undeflected, whereas a ray of light is deflected. It would be difficult to reconcile this with the principle of equivalence, which seems to require that the trajectory of a material particle should approach that of a light-pulse as the velocity approaches that of light.

The differential equation of the orbit of a material particle moving with any speed is [Report, Physical Society, p. 51, equation (31·2)]

$$d^2u/d\theta^2+u=m/h^2+3mu^2, \qquad (u=1/r),$$

where the constant $h=r^2d\theta/ds$. It is from this exact equation that the motion of perihelion of Mercury is obtained. For motion with the speed of light $ds=0$, so that h is infinite, and the equation becomes

$$d^2u/d\theta^2+u=3mu^2.$$

The solution is

$$u=\frac{\cos\theta}{R}+\frac{m}{R^2}\left(\cos^2\theta+2\sin^2\theta\right),$$

neglecting m^2/R^2.

In Cartesian co-ordinates this becomes

$$x=R-\frac{m}{R}\frac{x^2+2y^2}{\sqrt{(x^2+y^2)}}.$$

The asymptotes are found by taking y very large compared with x, giving

$$x=R\pm\frac{2m}{R}y.$$

Hence the angle between them is $4m/R$, agreeing with the result for the deflection of light rays.

I have verified by the usual methods the other principal result given by Mr. Page, that for radial motion the force (relative to the co-ordinates used) is a repulsion if the speed exceeds $1/\sqrt{3}$ times the velocity of light.

With regard to the question whether the system of an atom on the sun can be identical with that of an atom on the earth, inasmuch as the warping of space-time is different in the two places, it is clear that the identity cannot be *exact*; but this loophole for escape from the predicted shift of the Fraunhofer lines does not seem to be very promising. If the "intervals" of vibration of the two atoms are not the same, the difference must depend on some invariant of space-time which differs at the two places. I do not think that any invariant of order m/r exists. The simplest invariant which does not vanish is

$$g^{\mu\alpha}g^{\nu\beta}g^{\sigma\gamma}g_{\rho\delta}B^{\rho}_{\mu\nu\sigma}B^{\delta}_{\alpha\beta\gamma};$$

it is rather laborious to work out the actual value of this (since it consists of 65,536 terms), but it appears to be of order m^2/r^6. The Fraunhofer displacement depends on terms of the much greater order of magnitude m/r.

A. S. EDDINGTON.

Observatory, Cambridge.

Gravitational Shift of Spectral Lines.

THE assumption that the equations of motion in a gravitational field can be deduced from a condition of the form $\delta\int ds=0$ is in itself little more than a very natural way of expressing the principle of least action. The greatness of Einstein's theory really lies in the suggestion, made apparently on purely *a priori* grounds, that a certain set of six relations between the coefficients in the formula for ds^2, which are true when no heavy body is near, still hold near one. These are found to make the coefficients determinate, whereas previously they were quite arbitrary, and the observed motions of the planets, including the advance of the perihelion of Mercury, are at once deduced.

The displacement of star images during an eclipse is based on the further very plausible assumption that a light-wave moves like a material particle of zero mass starting from an infinite distance with the velocity of light there. Now that this displacement has become a result of observation, the data are just enough to make it possible to reverse the argument and deduce the fundamental assumption of the theory from observation, as I have done in a forthcoming paper in the Monthly Notices of the Royal Astronomical Society. Neither in Einstein's discussion nor in mine is any identification of ds with an invariable line element in four-dimensional space-time relevant to the theory; and as the application of the theory is purely physical, I think it undesirable that any such abstract idea should be made to appear as part of it. Physically, the invariance of ds means simply that the motion of a particle can be described in terms of any set of co-ordinates we like to choose.

In discussing these phenomena all positions and times are referred to an observer at the centre of the sun, and it is not necessary to determine the relations between his measures and ours, for the uncertainty in these would not affect the observed quantities appreciably. The problem of the shift of spectral lines, however, depends essentially on such a comparison. About part of the theory of it there can be no reasonable doubt, namely, the assumption that the vibration on the earth appears to any observer to have the same period as the vibration on the sun that causes it. What is doubtful is whether the atom on the sun vibrates in the same time as a similar atom on the earth. Einstein assumes that it does not, but that the increase in ds in a period is the same for both, and deduces the shift of the spectral lines.

There is nothing very bizarre about this; it only means that when we move about we must refer our observations to time standards in the place where these were originally used, and not expect that they will serve the same functions if we carry them about with us. An analogy from colour will illustrate this. Suppose we have a standard of redness in the form of a particular red body. We judge the redness of other bodies by comparison with this. Now suppose we go to a place where the prevailing illumination is green, but where our standard of redness is still visible through a window. We then say that none of the things in the room look red, but our judgments as to what outside bodies look red are the same as before. Our standard is now brought into the room. Are we going to say that it looks red still? If we do, we shall have to say that the red external bodies that have not been moved have been changed in colour by the motion of our standard, which is at least inconvenient, and which most people would call absurd. Therefore we say that our colour standard has been altered by its displacement, and choose another standard from among the visible external bodies.

Similarly, if an observer on the earth went to the

sun his time standard would not be that determined by bodies he had carried with him, but the standard found by observing from the sun similar bodies on the earth, and he would judge that his time standards were changed by being displaced. Of course, if they were not changed, the spectral shift would be zero. The colour analogy, however, shows that there is no special reason to believe that they are unchanged, and it certainly seems most likely that the invariable quantity in such a displacement is ds, for this is already known to be of fundamental importance in other problems. The shift, therefore, is probable, though if it were absent it would not be very difficult to construct a theory that would fit the fact.

If it were true that dt was the same for atoms on the sun and on the earth, we might expect our standards of length also to be the same; but this leads to a surprising result, for if they were, the measure of the wave-length of the emitted light would be proportional to $(g_{44}/g_{11})^{\frac{1}{2}}$, so that it would not be possible to continue to use the wave-length as a standard of length; thus such a hypothesis would lead, not to a simplification, but to an added complexity. It may also be noted that the spectral shift depends on the part of Einstein's law that agrees with Newton's, so that the two stand or fall together if this phenomenon is crucial.

Einstein's law, however, rests on firmer ground than the theory of the spectral shift. As to whether this shift exists, the available data on an average point to one of nearly the predicted amount, and are certainly much nearer this than zero. They show a great variation in the amount of the shift, which must be explained before the question can be regarded as solved. Many causes are capable of producing this variation, but what seems to me likely to be the chief does not appear to have received much attention. The prediction rests on the assumption that the vibrating atoms are in similar surroundings, which is plainly false. It is, indeed, required by the theory of stellar evolution that the whole constitution of a star must alter owing to successive types of atom becoming unstable and passing over into more stable forms. Instability demands that the slowest free vibration of the atom has its frequency reduced to zero, and in the process the other periods must be affected. The remarkable fact is not that there are shifts, but that the observed spectra are as much like terrestrial ones as they are.

HAROLD JEFFREYS.

Meteorological Office, S.W.7.

The Position of the Meteorological Office.

THAT the study of the atmosphere and the practical applications of meteorology should be supported and encouraged by the Government is a proposition so obvious that it is accepted in every civilised country. It does not, however, follow that the meteorological service of a country should be conducted as a branch of the civil service, still less of the military service, and British meteorologists must be grateful for the emphasis laid in the leader in NATURE of February 26 on the importance of scientific control of official meteorology.

I do not know enough of the present constitution of the Meteorological Office to offer any criticism of the Air Ministry in relation to it, but I am very strongly in agreement with the resolution of the Royal Meteorological Society as to the importance of full inquiry before changing the constitution of the Meteorological Office, which has led to such remarkable advances in meteorological science since 1905. The transfer to the Department of Scientific and Industrial Research, which you state to have been contemplated at one time by a Committee of the Cabinet, would, it seems to me, have been a natural development of the constitution under the Meteorological Committee, and it would have been free from the dangers to scientific progress which are, not unnaturally, feared from a subordinate position in the Air Ministry. Had a full inquiry been held, I doubt whether the claims of the Air Ministry would have been preferred to those of the Board of Agriculture and Fisheries, the Admiralty, the Board of Trade, and, in particular, to those of the Ministry of Health. The union of the British Rainfall Organization with the Meteorological Office has altered its centre of gravity so far as to make its equilibrium less stable in the Air Ministry than it would be in either the Board of Agriculture and Fisheries or the Ministry of Health. As part of the Department of Scientific and Industrial Research the Meteorological Office would be in neutral territory, and could be equally serviceable to all the great Departments, each of which would naturally be represented on the Advisory Committee controlling the organisation. The position would then be analogous to that of the Geological Survey, which, perhaps, is the official scientific body most nearly akin to the Meteorological Office.

For scientific bodies of this kind freedom from all unnecessary trammels of officialdom is necessary in order to permit the expansion and development which are essential to healthy life and practical usefulness; and in a body of such universal usefulness as the Meteorological Office in its present expanded form some representation of the industrial and economic applications of meteorology upon the advisory committee or other controlling board is nearly as important as the representation of independent men of science.

HUGH ROBERT MILL.

Hill Crest, Dorman's Park, Surrey,
March 2.

THE issue of NATURE for February 26 contained an account of the Royal Meteorological Society's resolution in reference to the transfer of the Meteorological Office to the Air Ministry, a leading article dealing with the same subject, and correspondence on the organisation of scientific work, part of which seems directly applicable to the same theme.

If it be true that the Meteorological Committee is no longer to exist, the society's protest appears amply justified. Otherwise the position of the Meteorological Office as a branch of the Air Ministry, with a scientific advisory committee, would appear not very dissimilar to that of the Natural History Museum; or perhaps a better comparison would be with the Royal Observatory, Greenwich, which is under the Admiralty, the Astronomer Royal being supported by a scientific advisory committee in the shape of the Board of Visitors, of whom only one, the Hydrographer, directly represents the Admiralty, the rest being either university professors of astronomy or else expressly nominated by the Royal Society or the Royal Astronomical Society.

The Meteorological Department at Greenwich, though now in its eightieth year, is too recent to expect direct representation on the Board, especially as its activities have not generally run in the direction of research, but the fact remains that the work at Greenwich has points of contact not only with the Admiralty, but also with the Board of Trade, the Post Office, the Meteorological Office, the Colonial Office, and other bodies. It ought not to be impossible to

give due attention from the Meteorological Office to the requirements of the Board of Trade and of the Board of Agriculture and Fisheries, even though for simplicity, and possibly for financial reasons, it is housed in the Air Ministry and its separate expenses included in the account of that Department.

WALTER W. BRYANT,
Hon. Secretary.
Royal Meteorological Society.

Organisation of Scientific Work.

THE fostering and development of the resources of India by means of scientific research is not a mere question of academic interest, but one on which the very economic existence of the country depends. Fortunately the Government of India has realised the danger of the situation, and is anxious to develop the vast potentialities of the country through the application of science, as Japan has already done with her far more limited resources. It is obvious that the success of the proposed scheme will largely depend on the encouragement of investigation among the Indian students and workers, who will necessarily be the principal recruits for the work of the utilisation of indigenous talent in the services of their own country. A quarter of a century ago, when science teaching was in its infancy in India, I ventured to predict that, through an ever-increasing ingenuity of devices necessary for extending the boundaries of knowledge, there would in the near future be seen in India an advance of skill and of invention among our workers, and that, if this skill could be assured, practical applications would not fail to follow in many fields of human activity.

My anticipations have since been fully realised; for example, the extremely delicate instruments which have enabled me to carry out all my investigations have been constructed entirely by Indian mechanicians, and I have been assured that the most skilled American instrument-makers could not have produced apparatus more delicate. As regards scientific advance in its various departments, it is generally recognised that the present period in India may truly be described as a renaissance.

With reference to the practical scheme now under the consideration of the Government of India, the leading article in NATURE of February 19 states very fairly the comparative merits of the two alternatives, namely, that of centralisation under a proposed Imperial Department, and that of decentralisation, under which research workers will be given as free a hand as possible. Under the centralisation scheme the work of an investigator would depend on the previous sanction of the head of the Service, who would probably not be of any scientific eminence, or might even be without scientific qualification; and, most serious of all, he would not be able to publish his results without the consent of the official head of his special department. The possible abuses of such conditions are sufficiently obvious to all.

Every real investigator is making a great adventure into the unknown, and all the initiative and all the risk must therefore be his own. Nothing could be so disastrous for the growth of knowledge as to place competent men under an incompetent machine.

Finally, who should be the judge of the value of the work accomplished? Such judgment should not be departmental or secret; the verdict should come from the open court of the scientific world itself, and this would effectively put an end to official or non-official incompetence.

J. C. BOSE.

33 Bloomsbury Square, London, March 6.

Photographs of Seven Vocal Notes.

DR. A. O. RANKINE, by means of the invention described by him in NATURE of February 5, has placed me under a great obligation in furnishing ocular confirmation, desirable for those whose hearing is undisciplined or poor, of observations made by the unassisted ear on the inherent pitches of vowel sounds. No one who can hear harmonics of a sustained note from the larynx reinforced successively by a continuous change in the pitch of the mouth-cavity acting as a resonator should remain in doubt as to their place in the tablature, for, the pitch of the voice being known, if a harmonic sequence is heard, such as 4 : 5 : 6 : 7, the vibration number of any one of these overtones is the product of a simple multiplication. The well-known spherical resonators, applied in turn to the ear, cannot be changed instantaneously, destroy the all-important contrast, and have failed. The late Lord Rayleigh's compound resonator (*Phil. Mag.*, 1907, p. 321) would do better service, but I do not know that anyone has used it for this purpose. The table in text-books of physics, physiology, etc., shows an extreme error of two octaves. The inherent pitches of the vowels of ordinary speech from *oo* to *ee* range from about f^{ii} to d^{iv}. Taking two octaves as the extreme compass of the mouth shaped for vowels, this supplies such "real characters" for vowel sounds as Bishop Wilkins and his friends looked for in vain, and the use of an alphabet thus rectified will make it unnecessary for English-speaking children to learn to spell, while the re-formed print writing will obviate spelling reform. I have explained this seeming paradox in a book now in the press.

The films were marked before exposure.

(1) "128 not, ?6." This means that a note *c* physical pitch is to be sung in which the singer hears the sixth harmonic intensified in the mouth, the vowel-quality more or less resembling the vowel in *not* prolonged. When the negative was changed back into sound by Dr. Rankine, the harmonic no longer in question (6, g'') was clearly heard by him, and afterwards by myself. The octave comes out in the photograph surprisingly strong. I suspect that it may be largely a self-combination tone. I do not with certainty distinguish the octave in any quality of my voice unless it is strengthened in the mouth, as when the vowel *oo* is sung to a top note of chest register.

Six more films were exposed on February 16. Brief samples of all six are here shown.

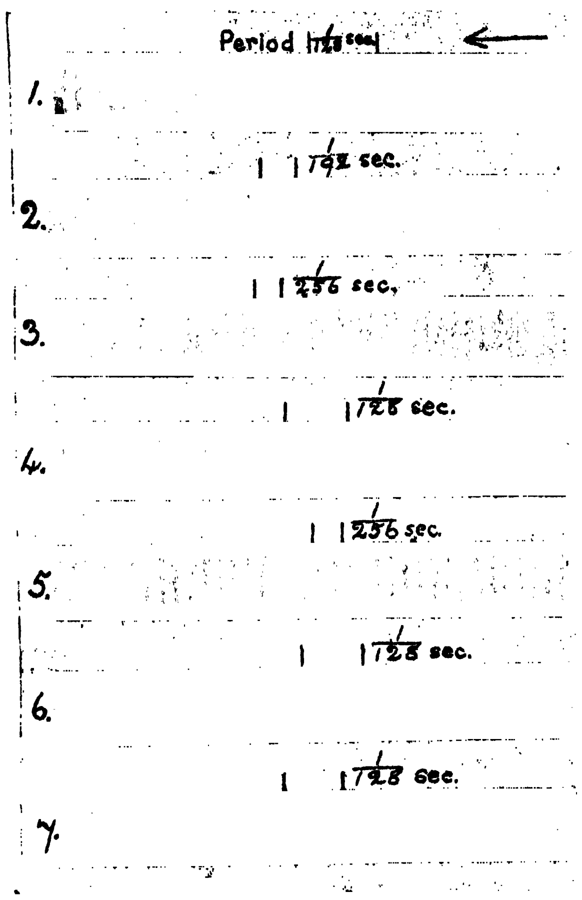
(2) "192 not, ?4." The voice being raised a fifth, to *g*, the mouth-tone g'' is now harmonic 4. The four light bands and four dark lines in each period are evident. The inequality of the spacing reminds us that the thing photographed is not a simple tone with the double octave imposed upon it, but a *voice* in which the fourth harmonic component is made especially prominent.

(3) "256 not, ?3." The voice at middle C, c' physical pitch, the overtone g'' is now harmonic 3.

(4) "128 book, ?5." The pitch of the resonator is lowered to e'' by an unusual protrusion and rounding of the lips. The pitch of the vowel in *book* as spoken in southern England is considerably higher than e''. One vibration in each periodic group is of the frequency 128×5. The rest appear displaced by the octave or the double octave.

(5) "256 book, ? high." The quality of the vowel is not affected, but now the pitch of the resonator is too remote from the nearest of the lower harmonics of c', 2 and 3, c'' and g''; and the only tone audible from the mouth is a very high, thin sound, noted more than once as undoubtedly a sharp F, harmonic

11 of c', $f^{iv}+$. No such frequency is visible on the film, which seems to have recorded only the fundamental and the octave. This vocal note might fairly be called a "dud." Though sustained with greater effort than (3) above, there is no *ring* in it, energy being wasted in the attempt to force a vibration in a mistuned resonator. When a singer happens upon a note of this kind he instinctively alters the oral configuration. Hence the endless complaints that some vocalists, no matter what language they sing, distort the vowels. It is impossible always to combine good resonance with purity of vowel sound, and the higher the voice, the more frequent the occurrence of such an unfavourable conjuncture as here illustrated. It is a matter of arithmetic.



(16) "128 not, ? 6." The seventh harmonic was not on the programme. The proposal was to repeat (1) louder. The note began well, but while forcing the voice I became doubtful whether I could hold out until the one second which was to receive duration had come and gone, and listening anxiously for the click of the shutter lost ear-control of the harmonic. In fact, I have to confess to a facial lapse, as sometimes happens when one is having a photograph taken. A slight enlargement of the lip-opening in the direction of the vowel in *far*, a nearer approach to the vowel in *not* as I speak it naturally, introduces harmonic 7 of the fundamental 128. It would be easy to demonstrate this at another sitting. The earlier part of the film is all at sixes and sevens. The strip reproduced with its apparently lop-sided octave proves that the period has been correctly marked in (1).

(7) "128 Somerset R." It was hoped to discover why the Wessex or American *r* should sound harsh to unaccustomed ears. So far, the ear tells me more than the eye.

It would be interesting to try a longer film marked '128 we may, pa, all go too, ? 17 to 5."

W. PERRETT.

University College, Gower Street, London, W.C.1, February 27.

Scientific Direction of Industrial Research.

EMBODIED in its rules, the National Union of Scientific Workers states that one of its objects is "to secure in the interests of national efficiency that all scientific and technical departments in the public service, and all posts involving scientific knowledge, shall be under the direct control of persons having adequate scientific attainments." The executive committee of this union realised that it had to overcome much prejudice existing against the application of this rule to the older Departments of State; but from the very circumstances which gave birth to the Department of Scientific and Industrial Research it imagined that the Department would adopt this rule as a cardinal principle, and enforce it in its relations with the many manufacturers' associations the co-operation of which was invited in the formation of research associations for the benefit of British industries.

Until the great war cut off supplies from Germany the British nation as a whole had realised neither its dependence upon that country for dyes, drugs, instruments, and glassware, among other things, nor the fact that great German industries had been founded upon the original work of British men of science. The war brought enlightenment; the nation discovered that its manufacturers, either from apathy or ignorance, had failed to exploit British brains for the benefit of the British communities; and it is safe to assume that the Department of Scientific and Industrial Research came into being to remedy this state of things and to bring the manufacturing interests into touch with the real scientific worker as distinct from the essentially "business" man.

The appointments of Sir Herbert Jackson, Prof. Crossley, and Dr. Slade as directors of research of different industrial research associations were welcomed by this union as an indication of the Department's acceptance of the principle laid down by all men of science, but later appointments have given rise to dismay, particularly that of Mr. R. L. Frink as director of the Glass Research Association, referred to by Dr. Travers in NATURE of February 5. Mr. Frink appears to have been successful as the head of a commercial organisation connected with the window-glass and bottle-glass trade, but careful inquiry has failed to provide evidence that by training or experience he can claim to be a man of science.

My union feels compelled, therefore, to protest with all its power against the appointment. It has sent its protest both to the Glass Research Association, which made the appointment, and to the Department of Scientific and Industrial Research, which approved it. From the former no reply has been received, although a month has elapsed since we made our protest; from the latter the following extracts from the reply are a confession of impotence to deal effectively with the matter:

"It is the intention of the Government that, so far as the conduct of the affairs of research associations is concerned, this shall be in the hands of the associations themselves. . . .

"Accordingly, the responsibility for the selection of a director of research and for the conditions of his

appointment rests in each case with the research association, and not with this Department."

In the case of the Glass Research Association the State contribution to its funds for the next five years is three-quarters of the total. In view of its relatively large contribution, the State should be able to exercise more than a merely nominal control over the appointment of the director; if it cannot do so, it should take immediate steps to remedy its position.

It is the opinion of the National Union of Scientific Workers that it is the subordination of the scientific worker to the "business man" which has been chiefly responsible in the past for the tardy development of scientific industry in this country. It feels that this appointment negatives the aims outlined by the Department, and that the whole industry will suffer from the consequent neglect of the scientific aspects of glass research work and from the unwillingness of scientific workers to submit to such direction.

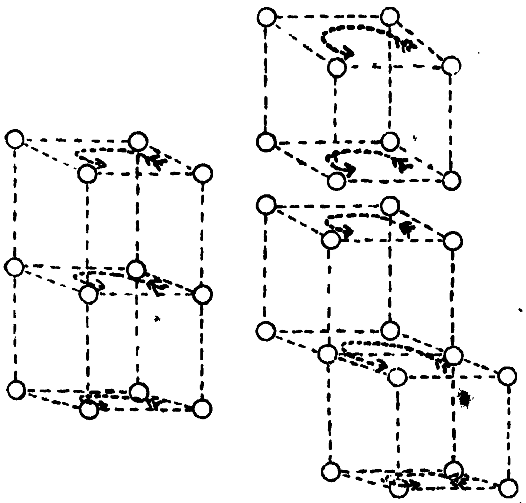
We firmly believe that the matter is one of the first importance, and that the result of our representation in this matter, not only with a commercial organisation, but also with the Department charged with the care of scientific interests in the country, may determine the relations of science and industry for many years to come.

A. G. CHURCH,
Secretary.

19 Tothill Street, Westminster,
S.W.1, March 6.

On Langmuir's Theory of Atoms.

THE great objection to Langmuir's theory of atomic structure is the difficulty of accepting his hypothesis of stationary electrons. In view of the extraordinary power of the theory, it is important to inquire if



Langmuir's argument from the fixity of direction of the valency forces necessarily holds. There appear to be various ways in which the rotation can be imagined of the stable groups of electrons formed by the combination of atoms. The figures represent diagrammatically, according to Langmuir's system, rotating groups of electrons in the outer shells of molecules of neon, fluorine, and oxygen. In the case of the fluorine molecule the six electrons, forming two quartets with two electrons in common, may revolve as a whole. The same thing may happen in the oxygen molecule, or the electrons may revolve as three quartets. Revolution of the stable groups of electrons would add to the stability of the molecules formed by their combination and increase the directional steadiness of the valency forces. In this way it may be possible to reconcile Langmuir's theory with that of Bohr.

S. C. BRADFORD.

The Science Museum, South Kensington,
London, S.W.7, February 16.

Seconding of Officers for Study at Universities.

THE War Office Memorandum recently issued rightly points with satisfaction to the arrangements made to allow Regular officers to take a full course of study at a university (A.O. 323 of 1919). Unfortunately, however, the conditions under which officers may avail themselves of this privilege are such that only the wealthy ones will be able to take advantage of it, for while seconded they will receive no pay or allowance from Army funds; indeed, it has not even been decided whether the whole or any portion of the period spent at a university will count towards pension.

I venture to suggest that pressure should be brought to bear on the War Office to secure that these privileges shall be open to officers of small means by allowing them to retain their pay and allowances during the time they are undergraduates.

J. WERTHEIMER.

Merchant Venturers' Technical College,
Bristol, March 8.

Scientific and Technical Books.

ONE part of the Descriptive Catalogue of the British Scientific Products Exhibition organised by the British Science Guild last year was devoted to selected lists of books on science and technology.

The guild has been asked to extend these lists, so as to include not only all branches of science, both biological and physical, but also the chief technical subjects. It has undertaken to do this, and a committee, of which I am chairman, has been appointed to prepare such a catalogue.

The lists will be limited to books of British origin actually in current catalogues of the publishers, so that they can be obtained in the usual way through booksellers. School books and elementary manuals will not be included, and the general standard will be that of college courses in scientific and technical subjects or of works libraries. Each list will be submitted to authorities upon the subject with which it deals, but in order to secure that no important work is omitted the committee invites the assistance of everyone interested in its task. Such aid may be afforded by sending (to the British Science Guild, 6 John Street, Adelphi, London, W.C.2) lists or single titles of British books of standard value or proved worth in any branch of science or industry. I shall much appreciate help of this kind which any readers of NATURE may be able to give.

R. A. GREGORY.

Daylight Saving and the Length of the Working Day.

SUMMER time this year is to begin on March 28 and end on September 27 (NATURE, February 26, p. 701). In this connection it may be of interest to point out one effect of the Daylight Saving Act which appears to have escaped notice.

During the six months when the Act is in operation the physiological working day is lengthened by one hour—that is to say, we are all practically compelled to be in active movement (of body or brain) for an hour longer than we normally should be. This lengthened day is accompanied by a curtailment of sleep, particularly in the case of working men who have to rise early, and children. It would be of interest to know the effect of these conditions on the worker's rate of production and the demand for shorter hours.

ANNIE D. BETTS.

Hill House, Camberley.

Rainfall and Land Drainage.[1]

By DR. BRYSSON CUNNINGHAM.

THE problem of the economical disposal of surplus rainfall in cultivated districts is one which naturally engages the attention of the agriculturist and, as a consequence of his needs and interests, of the meteorologist, the engineer, and the lawyer. All three aspects of the matter have been dealt with recently in an article in *Engineering* and in two papers read before the Surveyors' Institution.

The precipitation of atmospheric moisture is counterbalanced in part by the processes of (1) evaporation, (2) transpiration, and (3) percolation, the residue forming the run-off which collects on the surface of the ground and ultimately finds its way to sea by watercourses, either natural or artificial. In cultivated areas it is essential that the soil should be drained promptly and effectively, and left in a "moist," as distinguished from a "wet," or saturated, condition. Ill-drained land is incapable of experiencing the full benefit of those seasonal physical and chemical changes which promote the growth and development of crops.

The article by Lt.-Col. Craster discusses the proportion of run-off to rainfall, and the author finds that it varies in this country, as also in America, roughly between the limits of 33 and 67 per cent. It has been found that 0·065 in. of water is required to wet a crop of rough grass about 5 in. in height, the aftermath in a hayfield, up to the point at which it commences to drip on to the soil. It may therefore be assumed that the amount of water required to wet vegetation and the surface of ploughed land is not less than 0·04 in. or 1 mm. The whole of this amount is lost by direct evaporation after every fall of rain. If the number of days with a rainfall of 0·04 in. or more be 127 (as in the North-East of England in 1918) and the number of days with less rainfall be 67, the direct evaporation for this area will be $0{\cdot}04 \times 127 + 0{\cdot}02 \times 67 = 6{\cdot}42$ in. As regards transpiration (*i.e.* absorption by vegetation), figures from German sources show that a beech wood transpires 14·2 in. of water per year; a crop of oats, 8·98 in.; and a crop of barley, 4·88 in. For an average of 9 in. per year this would be divided as follows: July, 25 per cent.; June, 18; August, 15; May, 12; April and September, 8 each; March and October, 5 each; and the remaining months, 1 per cent. each. Percolation is more difficult to estimate, owing to variable geological conditions, but, as a rough rule, may be taken at not less than 10 per cent. Summarising these figures for the North-East coast of England, there would be a residue, or run-off, of 8·7 in. out of an annual rainfall of 26·8 in., *i.e.* 32·5 per cent., and for Fort William, Inverness, a run-off of 52·67 in. out of an annual rainfall of 78·7 in., *i.e.* 67 per cent.

From a survey of the flood discharges in England and Wales, Mr. Clayton arrives at the conclusion that, while no general rule can be laid down, it is permissible to assume that in average areas the run-off to the sea is from 50 to 60 per cent. of the total rainfall. As the general average rainfall is about 32 in. per annum, this means that, roughly, 1800 tons of water per acre finds its way annually into rills, brooks, streams, and rivers. Taking into consideration the fact that about 60 per cent. of the whole rainfall occurs in the six months October to March, the general proposition is established that 36 per cent. of the total rainfall has to be received by watercourses during a period of 182 days, whence it follows that an average wet period run-off to sea is 0·0633 in. per day. In designing drainage channels and in order to cover reasonable cases of abnormal rainfall, Mr. Clayton advises that this figure should be multiplied by 5, and the result so nearly equals 1 per cent. of the total annual rainfall that he recommends the adoption of this standard.

The calculation is pursued further to the determination of the flow in tidal rivers necessary to discharge this accumulation of land water. Applying the rule to a catchment area of half a million acres, the total volume to be discharged within an ebb-tide period of fourteen hours per day is 576,000,000 cu. ft., or, say, 11,430 cu. ft. per sec., which for a distance to sea of twenty miles would necessitate a channel with a theoretical mean area of 2721 sq. ft.

The maintenance and deepening of these outlet channels are important considerations, but, unfortunately, the jurisdiction and supervision exercised over them are casual and unsystematic in the extreme. Before the railway era, river and canal navigation brought in revenues from tolls which enabled due regard to be paid to the drainage needs of the districts through which they passed, but the decay of inland navigation has resulted in the loss of these financial resources, and drainage conditions have, in many cases, become deplorable. This view is endorsed in Mr. Konstam's paper, which deals with the legal and administrative point of view. The startling assertion is made that it is doubtful whether there is a single river in England which is at present in a satisfactory condition as a means of draining water from agricultural land. Whether strictly or approximately true, the situation calls for earnest attention. Drainage authorities—known as Commissioners of Sewers in many parts of the country—date back to medieval times, and their powers and functions have, in many cases, become ineffective and obsolete. The Land Drainage Act of 1918, however, does something towards alleviating the situation by enabling the Board of Agriculture and the Ministry of Transport to sanction the transfer of a navigation undertaking to drainage functions. No doubt in process of time some degree of co-ordination and system will be established.

The Work of the Medical Research Committee.

WHEN a certain small fraction of the National Health Insurance funds was set apart for purposes of research, the experiment was regarded even by many scientific men with suspicion or indifference. It was suggested that the State aid, thus provided for research, would result only in creating a new class of Civil Servants, and might, indeed, lead to the sterilisation of such of the younger men as had earned appointment under the scheme by the excellence of their early researches. It was also objected that any concentration of State aid in a central institute or among a single group of workers would be effected only at the price of starvation of the work already being carried out with insufficient means in the various universities and research institutes of the country. The work of the Medical Research Committee during the first five years of its existence has brilliantly refuted such *à priori* objections, and has, indeed, justified the view that the action taken in 1914 represents the greatest advance in the organisation of scientific effort in the service of medical science that has yet taken place in this country. The Committee seized the opportunity afforded by the war, and initiated and supported numerous investigations urgently required for the effective treatment of our soldiers in the field. So well did it succeed that, by the end of the war, it had secured for practically all the men fitted for original inquiry not only the opportunity, but also adequate payment, either by way of commissions in the Navy, or Army, or Air Force, or by research grants.

As the report points out, the casualties and mortality of peace are not smaller and less painful, but only less conspicuous and more familiar, than those of war. For example, the epidemic of influenza killed during a few months more young people in their prime than fell in battle during the whole war. Fully justified, then, are the efforts made by the Medical Research Committee to create and maintain organised scientific work, which shall repeat and continue for the maladies of peace the same success as was effected for those of war. Taking the difficulties of the situation into account, the report is really a wonderful record of achievement.

The Committee carries out its work in two directions. In the first place, it maintains a small nucleus of workers in whole-time service. Most of these will pursue their researches in the central institute, located in the old Mount Vernon Hospital, which has been adapted for this purpose; though, where the object of the work requires it, these workers may be attached to hospitals or laboratories elsewhere. Thus during the past year both Dr. Lewis and Dr. Elliott were attached as whole-time workers to University College Hospital, and other whole-time workers pursue their researches at Cambridge, Oxford, and St. Bartholomew's Hospital. In the second place, the Committee assists organised research already in progress at different universities and medical schools by means of grants made in payment for part-time work. We are glad to see that the Committee declares its desire to assist in this manner the work of the units which are being formed in London for higher clinical teaching and research.

The record of work for the past year must be regarded as highly creditable and a striking testimony to the value of the aid which the Committee has been able to render. Scarcely any aspect of medical science has been left untouched. Collective investigations have been undertaken on tuberculosis, on dysentery, on typhoid and paratyphoid, on the treatment of wounds, and on cerebro-spinal fever and influenza. Fundamental problems of nutrition have been attacked especially by the Committee on Accessory Food Factors, which has carried out researches not only in this country, but also in Vienna, and thrown much light on the causation of rickets and on the factors concerned in normal growth. The investigation of the disorders of the cardio-vascular system, including the causation of soldier's heart (in which such valuable results were attained during the war), has been continued, and a special department for this purpose has been instituted under the care of Dr. Lewis. The research into trench nephritis is being continued by Dr. MacLean and extended to include all forms of nephritis. The report records also the results of researches on the effects of oxygen lack, on chronic arthritis, on wound shock, on industrial fatigue, and on many other subjects.

The great value of the Committee's work is that in a time of transition, when the community is slowly awakening to the value and necessity of research in medicine, but has not yet provided the necessary organisation and support, it is making it possible for practically all provided with the necessary intellectual endowments to take up scientific work, at any rate for a time. No doubt many of these workers will later pass into practice; but the Committee by its action is creating a reserve of scientific workers, from which the country will be able to draw its teachers and teams of research workers, when once it recognises the need for them and is prepared to provide such salaries that a man can devote himself to the advancement of knowledge without taking vows of celibacy and poverty. There will always be a small handful of men in every country who will devote their lives to this cause. Faradays, however, are few and far between, and the vast majority of men of first-class intelligence are not prepared to make the supreme sacrifice. The country has need of these men to fill its depleted ranks of scientific workers, academic and industrial, but it will not obtain their services until it can provide a career in science equal in status and remuneration to that afforded by other professions.

The Mariner's Compass.

MORE than 300 years ago William Barlow, writing of the compasses of his day, said that, though the compass needle was "the most admirable and useful instrument of the whole world," yet nothing was more "bungerly and absurdly contrived." How little advance was made in the succeeding two centuries can be gathered from Peter Barlow's remark to the Lords of the Admiralty in 1820 that "the compasses in the British Navy were mere lumber, and ought to be destroyed." It was Barlow himself who made the first notable improvements in compasses during the nineteenth century, and his work was the prelude to the important investigations of Airy, Archibald Smith, Kelvin, and others. The practice of "swinging ship"—that is, turning a ship slowly round and noting the deviations of the compass in different positions by taken bearings—was introduced in 1810 by Matthew Flinders, who also invented the use of the "Flinders bar," a rod of soft iron placed near the compass to correct for changes in the magnetism of the ship due to the vertical component of the earth's magnetism.

The gradual increase in the employment of wrought-iron fittings in wooden ships; the use of iron cables instead of hempen; the placing aboard of ponderous iron boilers and engines; and, lastly, the construction of the vessel itself of iron, each in its turn added difficulties to the problems involved. Barlow, in his attempts in 1819 to find a remedy for the large deviation due to the extending use of iron in ships, made the first experimental investigation of the phenomena of induced magnetism. From his inquiry he was able to give a simple means of correcting ships' compasses by fixing soft iron discs in suitable places near the compass, and he afterwards introduced a type of compass having four or five parallel straight strips of magnetised steel fixed under a card, which remained the standard pattern until Kelvin brought out his famous patent in 1876.

The mathematical investigations of Poisson and of Airy about 1838 led to the introduction of methods of correction by the use of permanent magnets, and also of the well-known soft iron spheres. Many of Airy's experiments were made in the iron vessel *Rainbow* off the old Woolwich Dockyard.

The story of Kelvin's share in the improvement of the compass has often been told. Asked in 1871, by his friend Norman Macleod, to write an article for the newly founded magazine, *Good Words*, Kelvin chose as a topic the mariner's compass. The first part of his article appeared in 1874, and the second not until five years later. "When I tried," he said, "to write on the mariner's compass, I found I did not know nearly enough about it. So I had to learn my subject. I *have* been learning it these five years." The Admiralty standard compass, adopted in 1842, and in use when Kelvin took up the matter, had a card 7½ in. in diameter, and under it four needles, each of which was a long, straight bar of flat clock spring placed on edge. The card and the needles weighed about 1600 grains, and had a period of vibration of 19 sec. So considerable was the friction that the binnacle was often kicked by the sailors to make the card move. Kelvin's "gossamer structure" of eight small needles weighed about 170 grains, and had a period of about 40 sec. The cold reception Kelvin received from the then Hydrographer to the Navy, and Airy's remark on the compass, "It won't do," remind one of the reply made to Berthon in 1835: "The screw was a pretty toy which never would and never could propel a ship."

The ultimate adoption of the Kelvin compass was largely due to Lord Fisher, who had one on board the *Inflexible* at the bombardment of Alexandria in 1882. Torpedo craft, however, continued to be supplied with a form of compass in which the whole card floats in liquid, and improvements made in this type led to its being adopted as the standard compass about 1906. Since this has come the invention of, first, the Anschutz, then the Sperry, and, now, the Brown gyro-compasses, the introduction of which has taken place during the last ten years. As remarked by Mr. S. G. Brown in the Royal Institution discourse reproduced below, the gyro-compass is a necessity in a submarine, while in larger vessels it has the great advantages that it can be placed below the water-line more or less immune from gunfire, and lends itself to utilisation with fire-control apparatus and the torpedo director.

All the work on compasses for the Navy is to-day carried out at the new Admiralty compass observatory at Ditton Park, near Slough, where the work of the five departments—the gyro-compass branch, magnetic compass branch, optical branch, experimental branch, and air compass branch—is superintended by the director, Capt. F. O. Creagh-Osborne.

The Gyrostatic Compass.

By S. G. BROWN, F.R.S.[1]

THE subject of this lecture is the gyrostatic compass, often called the gyro-compass. An engineer of my acquaintance was asked if he understood what a gyro-compass was, and he replied, "Of course I do; it is a magnetic compass mounted upon a gyroscope." Now the gyro-compass has nothing to do with magnetism or the magnetic compass. The

[1] Discourse delivered at the Royal Institution on Friday, January 30.

only thing that these two instruments have in common is the property of pointing north and south. I am anxious that this should be clearly understood, because in a recent lecture I gave at Bournemouth on this very subject one of the audience asked me after the lecture how the gyro-compass was shielded from outside magnetic influence. I pointed out, as I had endeavoured to do during the lecture, that the gyro-compass had nothing to do with magnetism, and, therefore, did not require shielding. The magnetic compass and the gyro-compass are, in fact, two absolutely different instruments operated by entirely different laws, although they are for the same purpose.

As many people do not understand why a gyro-compass is needed when the magnetic compass is already available, it is worth while to describe briefly the magnetic or mariner's compass before attempting to explain the gyro-compass. The mariner's compass consists of a magnetic needle, or of several magnetic needles fixed side by side, and balanced upon a sharp point. A card divided into thirty-two (points of the compass) is attached to the needle, and swings round with it, so that the point marked N on the card always points to the north.

The earth, as we know, is a magnet, but not a very powerful one, and it has been calculated that if it were wholly of iron it would have an intensity of magnetism 17,000 times greater than it has. All the same, the magnetism is sufficiently strong to give a good directive action to a pivoted needle. The magnetic poles of the earth are not coincident with the geographical poles, but are situated some distance away. The north magnetic pole was discovered by Sir J. C. Ross to be situated in latitude 70° 5′ N. and longitude 96° 46′ W. in Boothia Felix, just within the Arctic Circle some 1000 miles away from the actual pole.

With this displacement of the magnetic poles we have an irregular distribution of the magnetism over the surface of the earth; and thus the magnetic needle does not point truly north and south at many parts of the earth's surface. In London, for instance, it points at an angle of 16° W. of the true north. This angle is called the deviation or variation of the needle. To enable ships to steer by the compass, magnetic charts have been prepared and the deviation at different places accurately measured. These magnetic charts have to be checked and altered from time to time, as the deviation slowly varies from year to year. Thus in London in 1659 the needle pointed true north, while in 1820 there was an extreme westerly variation of 24½°. Since then it has been slowly coming back to something like 16° at the present time.

On a wooden ship the accuracy of a good modern magnetic compass leaves little to be desired, but on an iron ship the case is quite different. The magnetic field of the earth tends to be weakened in the lengthwise direction of the iron ship, because a portion of the magnetism enters the ship, while across the ship the field is stronger; and as it is essential that the magnetism in which the needle lies should be uniform in strength in whatever direction the ship may happen to point, it is important that this stronger field should be reduced by some method of magnetic shielding. This is accomplished by fixing a pair of iron globes athwart the ship on the two sides of the compass. The effect of the iron of the ship and the corrections that have to be made to the compass is to reduce the directive force of the earth's magnetism, and thus the compass is rendered slow and sluggish in its action. This is particularly the case on board a battleship. In the interior of a submarine the force is still further reduced, so much so as to render the magnetic compass useless for this class of vessel.

It is quite possible on an iron ship to correct the errors of a compass, but as the ship itself may be a magnet, and its strength a variable quantity, it is important that the navigator should test the readings of his compass at every available opportunity, and particularly at the commencement of each voyage. The ship's magnetism may quickly change through the hammering action of the waves, through the heating action of the sun on one side of the vessel, or through an earth on any of the electric wires that may be running near the compass; all these things together add to the anxiety of the captain, as he is never quite certain how far the compass is correct in its readings.

The swings of the modern compass are damped by immersing the needles and card in a liquid such as alcohol, but as this fluid is attached to the ship and turns with it, swinging the ship in any direction carries the liquid round and reacts on the needle and card, so that the compass has a tendency to be carried round with the vessel. This lag in the instrument renders it difficult to hold a ship dead on her course, and the path, as a consequence, is sinuous, and may oscillate, even in a calm sea, as much as 7° each side of the correct heading. As a ship has usually to steam entirely by the readings of the compass, any error is serious. For instance, if there is an error of 3°, and the ship is steaming at sixteen knots, she will move one English mile off her course every hour. It is obvious how necessary it is to have absolutely correct readings.

Lord Kelvin was the first seriously to study the errors of the magnetic compass. He started in 1871, and in 1876 produced his well-known instrument. Although it was a great advance on any compass in the British Navy, he had the greatest difficulty to get it adopted; finally, in 1879 he proposed to place an instrument at the disposal of the Admiralty at his own expense. This offer was accepted. In spite of this, it was only through the acquaintance of influential naval officers, particularly of Capt. (now Lord) Fisher, that the compass was ever adopted. In 1889, eighteen years after the commencement of his experiments, and long after it was in common use in commercial ships, he received official notification that his 10-in. compass was to be adopted in future as the standard of the Navy. It is fortunate that we have an alternative method of securing a north-seeking property in the gyro-compass, an instrument of much greater accuracy than the magnetic and with none of its errors; for if deviations do occur they are known deviations, and can therefore be allowed for.

Evans and Smith, in 1861, were the first to discover how important it was to mount the needles on the card so that the moments of inertia of the moving system should be the same about all directions—that is to say that the system should be in dynamic balance, otherwise the rolling of the ship would cause deviations in the reading. I have lately discovered that another deviation may be brought about, not by an oscillation in one direction, but by the card being set wobbling; the needles and card would then have a force applied trying to carry the moving system round in the direction of the wobble.

I have a magnetic compass here to demonstrate this. It consists of a heavy brass disc mounted on a vertical frictionless spindle. The needles are fixed to the disc, and the whole movable system is carried on a pendulous mounting, as in the gyro-compass. The disc and needles are in correct static and dynamic balance. Swinging the pendulum in any one direction produces no deviation, but by making it swing in a circular conical path, thus giving a wobble to the plate, a serious deviation is caused in the reading of the compass. The error is permanently maintained against the earth's attraction so long as the circular

motion of the pendulum persists. When the compass is carried round in a horizontal circular path without wobble, the plate still goes round, or tries to go round, with a circular movement. This should be of interest to mathematicians.

Before leaving the instrument I will set it spinning so as to demonstrate the frictionlessness of the vertical axis. It is rotating now entirely by means of the energy of the motion of the plate, and I think you will find at the end of the lecture that it is still revolving, but, of course, not so fast as at present.

The magnetic compass is a simple piece of apparatus, but it is complicated in its readings and corrections, and points to the magnetic north. The gyro-compass is a complicated instrument, but simple in its readings, and it points to the true north.

Before proceeding to describe the gyro-compass I wish to direct attention to the equipment here displayed. A gyro-compass is in full operation, and at the present moment is recording its movement upon a travelling strip of paper. About half an hour before the lecture started the compass was deflected from the north position, and it has since been left to itself. The record shows that it is engaged in swinging back

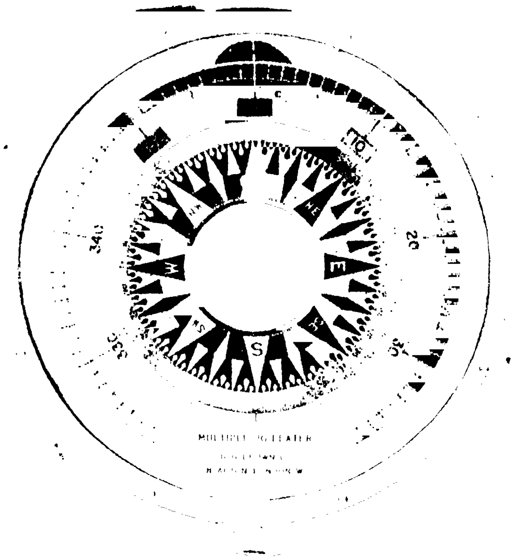

FIG. 1.

again to the north, recording a curve upon the paper strip, and this record can be followed during the whole of the lecture.

The compass is working two repeaters, which truly copy the reading of the master compass. Of course, any number of repeaters could be used on board ship if it were necessary. The steering repeater (Fig. 1) has a card that revolves four times to one of the master, and the divisions are, therefore, very much enlarged. The other is a correction repeater; it moves backwards and forwards very slightly, and this motion we term the "hunt." In the steering repeater the "hunt" has been cut out by providing the mechanism within the case with a requisite amount of slackness.

About sixty-eight years ago Foucault did what was thought a wonderful thing at the time; he gave a lecture-room proof that the earth was rotating on its axis—he looked through a microscope at a gyrostat. He could not get a frictionless, free, vertical axis, so that the experiment could not last for long. I shall be able to show you a piece of apparatus which carries out Foucault's idea in a perfect way, and will be visible to this audience.

A gyrostat consists of an accurately balanced spinning wheel, mounted with as little friction as possible, and in such a way that the axis of the wheel may point in any direction in space. Mere translation in space has no action on the instrument; carrying it about, for instance, does not alter the direction of the axis. On the other hand, the gyrostat is acted upon by any force that tends to tilt the axis or to give the axis a new direction in space.

The wheel (Fig. 2) spins round its axis; call the direction of this *oa*. If we impress a force upon the wheel tending to tilt or rotate it round another axis *ob*, then the rule is that the spinning wheel will "precess" or move in such a direction as to try to make the two axes *oa* and *ob* coincide, and the direction of spin of the wheel to coincide with the new direction of rotation that we are trying to produce by the applied force.

An electric circuit has similar mathematical laws to those of the gyrostat, and may be used as an illustration. The circuit here used (Fig. 3) consists of

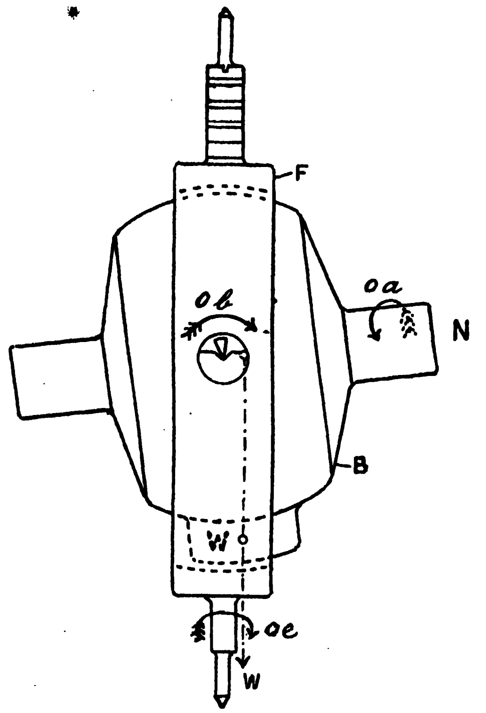

FIG. 2.

an outer fixed coil and a central suspended coil. A strong direct current indicated by *a* is kept flowing in the central coil; this corresponds to the spin of the wheel. If a direct current indicated by *b* is sent round the outer coil, then the central coil will move in such a direction as to make not only the axes of the magnetic fields of the two coils, but also the direction of the two currents, coincide. In fact, the coils will move, or try to move, in such a way as to make the self-induction of the whole circuit a maximum.

This is very much like the gyrostat, or, in fact, any piece of mechanism which under impressed forces tends to move so as to make the whole moment of momentum a maximum. Suppose, therefore, a gyrostat has its axis *oa* fixed parallel to the earth's surface, but free to turn in "azimuth," as it is called, upon a frictionless vertical spindle; the earth will act upon such an instrument, and it would be a gyro-compass.

The earth as it rotates is continually tilting the axis of the wheel in space; the wheel will therefore turn

so as to set its axis of rotation as nearly as possible parallel to the axis of the earth. It is only when the two axes coincide that the wheel is free of any further tilting action—that is, when it is pointing true north; deviate the axis, however slightly, from this position of rest, and the action of the earth comes in again to precess the wheel back again to the north.

Here is a simple form of gyrostat with three degrees of freedom. If I hold it in my hand and revolve on my axis, this does not move the wheel, which still keeps pointing to the same part of the room. On the other hand, if I restrain or clamp one of its degrees of freedom so that I am able to tilt the axis of the wheel during my revolution, the wheel is caused to precess and to set its axis parallel to the axis on which I am revolving. Reversing the rotation, the wheel also reverses.

This is what takes place with the gyrostat on the earth's surface provided it is frictionlessly mounted. Such an instrument is before you, and I will try to demonstrate by its means the rotation of the earth. A wheel is rotating inside this case at 15,000 revolutions per minute. The case is constrained to move

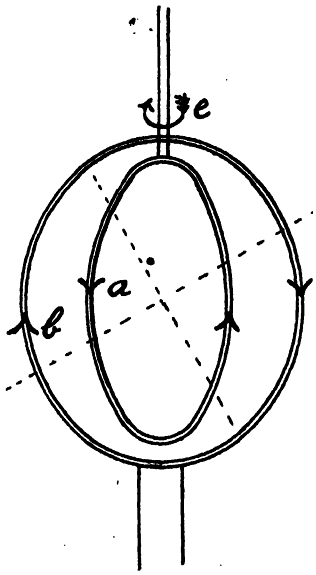

FIG. 3.

about this vertical frictionless axis. Mere motion of translation has no effect in changing the direction of the axis of the wheel, but if this room rotates the axis of the wheel tends to set itself parallel to the axis about which the room is rotating.

We all believe that this room is rotating about the axis of the earth; if so, the axis of the wheel must set itself parallel to the axis of the earth, but it must be kept horizontal, and, therefore, it will point north and south. Here it is pointing in an east-and-west direction; it is held by a string. I will now burn the string, and it will find for us the true north. Observe that it is really the true north direction, whereas that magnet points to the magnetic north. I set it away from the north, but on the other side, and repeat the experiment.

Such a simple form of gyro-compass could not be of any use on a moving ship, because the rolls of the ship would react too violently on the spinning wheel and cause considerable deviations in the readings of the compass. The use of a gyro-compass on land is very limited, and its great value at the present time is on board ship. The spinning wheel is acted upon by forces which tilt the axis. Now, a rolling and pitching ship is about the worst place to put a gyrostat to act as a compass, because the ship's movements all tend to tilt the axis.

The problem, therefore, is to make the compass insensible to the movements of the ship and respond only to the slow angular rotation of the earth. To indicate the severity of the ship's movements, I may recall a recent trip of this gyro-compass on board a fast destroyer. During a severe gale the ship was recorded to roll more than 50° of total angle. Many of the crew were forced to lie on the decks, the lockers emptied their contents, and even some of the oil-lamps suspended from the ceiling were unseated by the pitching of the vessel; yet the gyro-compass maintained its accuracy, and allowed the ship to be steered safely into harbour, to which she had to run for safety. In all this whirlwind of movement the gyro-compass heard, and only responded to, the still, small voice of the earth's rotation.

For use on board ship the compass must be mounted on a pendulum in gymbal rings, and its period of oscillation is lengthened to something like 85', which is usual in practice, so that the rolls, which are of the order of 7 to 15 seconds' period, shall have but small effect on the compass. In this case the rotation of the earth does not act directly upon the gyro-wheel, but by means of the force of gravity through the pendulous weight. Unfortunately, this form of mounting introduces troubles of its own.

Suppose we study our simple gyrostat and see what happens when we attach a weight to the end of the horizontal spindle; this will give us some idea of what occurs when the force of gravity is acting through the pendulum trying to tilt the gyro-wheel.

We know from our law that the wheel will precess under the tilting action, but the new direction of rotation that we are trying to produce by means of the weight, unlike that produced by the earth, which is always in one direction, is in this case continually carried round by the precessing wheel, and the precession is, therefore, permanently maintained. We also find that if we hurry the precession the spindle rises, lifting the weight; while, on the other hand, if we delay the precession, the spindle drops and the weight falls. The rate of precession is proportional to the weight. Halving the weight, for instance, halves the rate at which the wheel rotates round the vertical support.

Coming back again to our pendulous-mounted gyro-compass (Fig. 2); suppose the spindle is pointing west and is horizontal, then the earth as it rotates will leave the wheel pointing in this one direction in space, but the weight will try to follow the earth's rotation, and will start precessing the gyro towards the north. The rate at which the wheel comes to the north depends upon the weight W attached to the casing. All the time the wheel is coming to the north the earth is adding to the rate of the precession, and the spindle is, as a consequence, tilted, and deflecting the weight at the north position. Under these conditions the effect of the weight is to continue the precession, and the gyro-wheel will swing through the north position, and continue to move until the effect of the earth arrests and reverses the motion.

The compass will therefore continue to swing through the north position with constant amplitude backwards and forwards, undamped. To render the compass of use, some method of damping the swing must be introduced so that the compass may finally settle on the north. This damping can be carried out by means of friction, preferably fluid friction, between the vertical spindle and its support; but, although this will damp the swings, it is inadmissible because

the movements of the ship would react through the friction and cause errors in the reading.

Anschutz, in his early form of compass, by use of an air blast, gets rid of this connection with the ship. The air blast was arranged to oppose the movement in azimuth when the wheel tilted, and thus he obtained an effective method of damping. The strength of the air blast, which varies proportionally to the tilt, should be nothing when the compass is at rest on the north—that is, when the tilt is nothing—and this would be true with the compass on the equator.

In other latitudes, however, the compass rests at the north with a tilt still remaining. It does not come back to the horizontal position because the axis of the wheel is trying to set itself parallel to that of the earth. This leaves a residual air blast continuously acting, producing a permanent twist in azimuth and a constant error. It is, therefore, preferable to damp the swings of the compass by acting upon the tilt rather than upon its movement in azimuth, because in this case there will be no latitude error. The tilt is a maximum at the middle of each swing—that is, when it is moving through the north position—and it is the return of the weight to its truly vertical position that is responsible for the continuation of the oscillation; we therefore require some method of neutralising the action of the weight, not before, but after, the compass has reached the north. This I accomplish in the Brown gyro-compass by automatically moving a liquid from one bottle to another, and in such a direction as to counterbalance the weight, precessing the gyro-wheel, and I delay its action by means of a valve or constriction in the tube joining the two bottles.

The force with which the compass seeks the north is proportional to the product of the rotation (one revolution in twenty-four hours) and the spin of the wheel. The faster we can spin the wheel, the more do we obtain directive force. It is for this reason that the wheel is rotated at its maximum speed and strength consistent with the rise of temperature.

Taking the Brown gyro-compass as an example, the wheel, which is 4 in. in diameter and 4¼ lb. in weight, runs at 15,000 revolutions per minute. The maximum directive force of the earth on this wheel—that is, when the spindle is pointing east to west—is only the weight of 30 grains, with a leverage of 1 in. This small force is continually diminishing in value as the axis approaches the north direction, and vanishes absolutely in that position. If the compass was deflected, say, 1° from the north, then the force of restoration is only ½ grain at a leverage of 1 in. It will therefore be seen how important it is to eliminate as completely as possible any friction on the vertical axis that would tend to oppose the directive action of the earth.

There are three forms of gyro-compass now in use: the Anschutz (German), the Sperry (American), and the Brown (British). In the Anschutz the vertical axis is supported by a bath of mercury, and in the Sperry by a suspended wire, the twist, if any, being taken out by a follow-up motor through an electric contact, which switches on the current to the motor; while the Brown is operated by a hydraulic system of support. The lower end of the vertical spindle acts as a ram and stands upon a column of oil. The oil is under great pressure, some 500 lb. per square inch, and is kept pumping up and down, and thus raising and lowering the vertical axis continually some 180 times every minute.

The continual movement of the spindle results in a practically frictionless vertical support, so that the total moving part, some 7½ lb. in weight, can be carried round in azimuth by the smallest force, due to the earth's rotation; in fact, so small is the friction that the compass, if deflected, will always come back again to its true north position, certainly within one-tenth of a degree. I think I am safe in saying that it is the most perfect frictionless support yet given to the vertical spindle of any gyro-compass, or, indeed, of any machine.

In an earlier part of this lecture it was stated that the period of oscillation given to a gyro-compass is of the order of 85′. I will now try to explain why this is so. The earth has no angular movement from south to north, but has one from west to east, due to the daily revolution on its axis. A ship, however, sailing to the north at, say, twenty knots an hour introduces an angular movement in that direction because it is moving over the curved surface of the ocean, and would complete a revolution of the globe in forty-five days.

If there were a gyro-compass on the ship the instrument would be sensible of these angular movements, set itself so as to make a compromise between them, and, as a consequence, point, not to the true north, but one or more degrees west of the actual pole. This division is termed the "north steaming error." Knowing the latitude, the speed of the ship, and its direction towards the north and south, the extent of the error can be accurately calculated, and speed-correction tables have been prepared so that this error can be determined for any latitude, speed, and heading of the ship, and can be allowed for.

Automatic means have also been devised to make these necessary corrections in the reading of the compass. For instance, my special form of repeater has been designed so that the card can be set eccentric, and, when once set, the correction will be automatically applied without any further reference to the tables.

When a ship is in harbour a gyro-compass on board points due north, but when the ship starts steaming to the north the compass begins an oscillation so as to bring the axis of the wheel into the new resting position to include the north steaming error in the reading. Getting up speed will, however, have another effect on the compass. We know that the gyro-wheel is acted upon by a pendulous weight. As the ship changes its speed the acceleration will act upon the pendulous weight and cause an oscillation to be started. This oscillation is termed the "ballistic deflection."

The permanent north steaming error and the transitory error due to the ballistic deflection are in the same direction, and mathematicians have calculated that with an undamped gyro-compass, if the time of its oscillation is set to 85′ in any particular latitude, the ballistic deflection can be made exactly the same as the deflection due to the north steaming error; this being so, the compass should move into its new resting-place without further oscillation. This would be true if, as before indicated, the compass were undamped in its swings, but the mathematicians have overlooked the fact that all gyro-compasses are damped, and the ballistic deflection must, therefore, include a term due to the damping.

This damping term up to the present has been neglected, but in practice it is found that when a ship is steaming and turning to alter its course the compass does not come dead-beat to its new position, but has an oscillation started which is common to all existing gyro-compasses. The extent of this oscillation may be termed the "damping error." On a merchant ship the damping error is of little moment, but on a war vessel which is manœuvring it may be serious, as it may swing the compass off its correct reading by several degrees.

(To be continued.)

Obituary.

PROF. J. EMERSON REYNOLDS, F.R.S.

PROF. JAMES EMERSON REYNOLDS, whose death at seventy-five years of age was announced in NATURE of February 26, was born in 1844 in Booterstown, a suburb of Dublin. His father was a medical practitioner and proprietor of a medical hall, and it was while assisting his father that he first became enamoured of the study of chemistry. Destined to follow in the profession of his father, Reynolds studied medicine, and became a licentiate of the Royal College of Physicians and Surgeons of Edinburgh. Although he practised in Dublin for a short time, his great desire was to devote himself to chemistry, and his chance to discard medicine soon came when, in March, 1867, he was appointed "keeper of minerals" at the National Museum in Dublin, and in the following year analyst to the Royal Dublin Society. It was here that he made his first important contribution to chemistry. In 1869 he discovered thiocarbamide, the sulphur analogue of urea, which he obtained as a result of the isomeric transformation of ammonium thiocyanate. This was a discovery which attracted a good deal of attention at the time, since Liebig and, later, Hofmann had both been unsuccessful in their attempts to isolate the compound—in fact, Hofmann had previously suggested that ammonium thiocyanate was probably thiourea.

Two years later, in a paper communicated to the Royal Society, Reynolds described the preparation of an interesting compound of acetone and mercuric oxide, of the composition $2(CH_3.CO.CH_3),3HgO$, which was the first example of a colloidal mercurial derivative. The conditions under which this body is formed constitute a very delicate reaction for the detection of acetone.

In 1875 Reynolds was appointed to the chair of chemistry in the University of Dublin in succession to the late Dr. Apjohn, having previously been for two years professor of chemistry at the Royal College of Surgeons of Ireland. He quickly established for himself a high reputation as a teacher and lecturer, and for a few years his energies were mainly directed towards the development of the teaching of chemistry on original lines. Shortly after his appointment he commenced the writing of his well-known "Experimental Chemistry for Junior Students," which was ultimately published in four small volumes. The first volume was a distinctly original work. By the aid of a progressive series of simple and well-tested experiments, the junior student was enabled to verify for himself the fundamental laws of chemistry by *quantitative* results. Whilst the quantitative method is now universally adopted in the early training of the student, Reynolds must be given the credit of having been the first to introduce it, now forty years ago. The experimental illustration of his lectures was a matter to which Reynolds gave great attention and a good deal of his time. If, from one cause or another, an experiment failed, which was of rare occurrence, it was always successfully repeated on the following occasion. As a result, his lectures were very attractive, and the discipline which he maintained in his classes was proverbial in the college.

This, it can be understood, was not attained without the display of a certain amount of well-meant severity, and, though Reynolds always refused to nourish popularity at the sacrifice of a surrender of discipline, he was nevertheless held in high esteem by all young men who came under his tuition. Past students have many times spoken to the writer of their great appreciation of Reynolds as a lecturer, teacher, and disciplinarian.

Whilst his professional duties absorbed most of his time, Reynolds continued research, and, from a comparison of the specific heats of silver and beryllium (glucinum), which he had prepared in a nearly pure state, he showed that the atomic weight of the latter must be taken as 9, and that the element was a member of the family of alkaline earths.

In 1885 his researches on organic derivatives of silicon, in which this element was united to nitrogen, were commenced. The results were described in a series of more than a dozen papers published in the Transactions of the Chemical Society up to 1909. Amongst several new substances which were prepared, perhaps the most interesting was the beautifully crystalline silicotetraphenylamide, $Si(NH.C_6H_5)_4$, the carbon analogue of which has never been obtained, and by the action of heat silico-diphenylimide, $Si(NC_6H_5)_2$, was obtained, the carbon analogue of which is well known. After twenty-eight years' occupation of the chair of chemistry in the University of Dublin, Reynolds retired in 1903, and went to live in London, where he continued work in the Davy-Faraday Laboratory.

Reynolds's last contribution to chemistry, published in the Proceedings of the Royal Society in 1913, was an interesting synthesis of the mineral anorthite, $CaAl_2Si_2O_8$, which he prepared by the combined action of oxygen and water vapour at a high temperature on the synthetic substance $Ca(SiAl)_2$, which he had previously prepared. Reynolds had many honours conferred upon him during his career. He was elected a fellow of the Royal Society in 1880, and vice-president in 1901, president of the Chemical Society 1901–3, president of the Society of Chemical Industry 1891–92, and president of the chemical section of the British Association in 1893. Reynolds died suddenly on Tuesday, February 17, at his residence in London. He was an honorary M.D. and Sc.D. of the University of Dublin. He married, in 1875, a daughter of Canon Finlayson, of Dublin. He leaves two children, a son and a daughter.

E. A. W.

We much regret to see the announcement of the death on March 9 of M. Lucien Poincaré, Vice-Rector of the University of Paris, at fifty-eight years of age.

Dr. Samuel Hatch West, who died on March 2 at the age of seventy-one, was well known in London as a consulting physician. He was trained at Oxford under Rolleston and Acland, and as Radcliffe travelling fellow he studied in Vienna and Berlin. He was physician to the Royal Free Hospital and to the City of London Hospital for Diseases of the Chest, but his life's work was carried out at St. Bartholomew's Hospital, where he received his medical education, and held successive medical appointments until he became full physician. Dr. West was a successful clinical teacher, and many generations of students will be grateful to him for the thorough manner in which he taught them to examine a patient, system by system, so that no important organ could be overlooked. Dr. West deserved his high reputation as a careful clinical observer. Diseases of the lungs were his particular study, and on this subject he produced a monograph in two volumes which is a monument of industry and a veritable mine of information. He delivered the Lettsomian lectures at the Medical Society of London in 1900, taking as his subject "Granular Kidney," but it is by his teaching and his work on diseases of the lungs that he will best be remembered.

A correspondent, "G. P. B.," writes:—"All zoologists who have ever worked at the 'Stazione Zoologica' of Naples will be grieved to read of the death of Prof. Eisig, whose obituary notice by Prof. R. Dohrn appears in the Zürich *Zeitung* of February 19. Hugo Eisig was born in Baden in 1847. When Anton Dohrn, aged thirty-one, decided to sink his whole fortune in the building of the Naples station, knowing that it would suffice to rear up only the ground story, his friend Kleinenberg went with him; Eisig, seven years their junior, offered himself also, and was accepted. Many years of great difficulty followed, and then many years of very great success. Through all Eisig continued the career which he had chosen as part and parcel of the Stazione Zoologica. His contribution to zoology is not to be measured by his published work, even though it includes his great 'Monograph of the Capitellidæ.' To all of us who worked at Naples he was a friend, loyal, sympathetic, unselfish, and gentle. In 1907 Eisig retired on a pension from his administrative post in the Zoological Station, but continued his own zoological work. Two years later Anton Dohrn died, and was succeeded by his able son, but in 1915 Prof. Reinhard Dohrn, with Eisig and others of the staff, had to leave Naples for the hospitality of the Zürich Zoological Museum and Swiss territory. There Eisig died on February 10 last from the after-effects of an operation which appeared to have been successful. He died in exile from his home of forty-four years, but in the warm memory of many friends all over the world."

Notes.

A meeting convened by the Chancellor of the University of Cambridge and the president of the Royal Society was held on Thursday, March 4, at the rooms of the Royal Society, to consider the question of a memorial to the memory of Lord Rayleigh. After a preliminary statement by the president of the Royal Society announcing the purpose of the meeting, speeches in favour of the proposal to erect a memorial were made by Mr. A. J. Balfour, Sir Charles Parsons, Dr. P. Giles (Vice-Chancellor of the University of Cambridge), Sir Arthur Schuster, Sir Richard Glazebrook, and Sir Joseph Larmor. It was agreed that a fund should be raised for the purpose of placing a memorial, preferably a window, in Westminster Abbey. A general committee was appointed, as well as an executive committee, to consider details, and also the further question of raising a fund in memory of Lord Rayleigh, to be used for the promotion of research in some branch of science in which Lord Rayleigh was specially interested.

A public meeting was held in the University Museum, Oxford, on March 6, to initiate a memorial to the late Sir William Osler, Bart., Regius professor of medicine in the University for the past fifteen years. The Vice-Chancellor presided. Sir Clifford Allbutt, who introduced the proposal, paid a feeling and eloquent tribute to the memory of Sir William Osler, to the wide range of his intellect, and to the singular charm of his character. He referred to his international reputation and to the binding influence he had on the medical profession in many lands, to his love of peace and goodwill, and to the extraordinary power he exerted in diffusing without diluting friendship. The president of Magdalen, Sir Herbert Warren, mentioned the many-sidedness of Osler's interests and activities, the breadth and accuracy of his scholarship, and the clear and steady optimism with which he regarded life and its progress in all ages. Sir William Church, who introduced the specific proposal that the memorial should take the form of an Osler Institute of General Pathology and Preventive Medicine, stated that such a memorial as that suggested would be a singularly appropriate tribute to the outlook and ideals that Osler had kept before him in his life-work. Prof. Thomson emphasised the need of new laboratory accommodation in Oxford for teaching and research. The Dean of Christ Church and Sir Archibald Garrod also spoke. It was announced that the hon. secretary, Prof. Gunn, had received expressions of sympathy with the proposed memorial from a large number of people representing many interests, and that a collateral committee had been formed in America to aid in raising the memorial.

A movement has been started to commemorate the life and work of the late Sir James Mackenzie Davidson by an appropriate memorial. The proposal is that steps should be taken to found a Mackenzie Davidson chair of radiology at some university, but, whereas nothing could be more fitting as a memorial to the work of one who devoted a large part of his

life to the development of the subject of radiology, it is urged by the thirty signatories of the appeal that, if the wider claims of the subject are to be met, there should be an X-ray institute. The applications of X-rays in medicine have vastly extended both in diagnosis and in treatment during the last ten years, but the new knowledge as to the properties of X-rays revealed by crystal analysis has opened out many new fields both of investigation and of application. If the subject is widening in these respects, there are signs no less clear of a growing need for improved teaching in the many fields of X-ray activity. The institution of a diploma in radiology by the University of Cambridge is but one indication of the demand that exists at the present day for instruction in the subject of X-rays. A well-equipped and well-organised institute seems the most likely way in which the multifarious interests of X-rays can best be welded into an efficient working whole, and it is hoped that the response to the appeal will ensure that the brilliant X-ray work done in this country may be augmented.

THE first post-war meeting of the International Council for the Exploration of the Sea was held in London last week, March 2–6. The countries represented were Belgium, Britain, Denmark, Finland, France, Holland, Norway, and Sweden. France sent a delegate for the first time, and the United States of America was informally represented. The British Government entertained the delegates and others at a dinner at Lancaster House, the Royal Society held a reception at Burlington House, and the Trustees of the British Museum and the Royal Geographical Society also received the delegates. The meeting resolved itself into a number of sections for the consideration of particular questions; these were the formulation of a scheme of research to enable the various Governments to make a convention for the better regulation of the North Sea fishing-grounds; the future conduct of the hydrographic and plankton researches; biological, statistical, and historical investigations with respect to the herring; the European eel fisheries; the fisheries of the seas to the south-west of the British Isles; a limnological survey; international fishery statistics; and certain basal physical and biochemical matters. Much interest was exhibited with regard to the "plaice problem," and the section concerned held several meetings. The hydrographic sectional meetings were very interesting, but it was clear that no immediate results were to be expected. The *personnel* of the Council had not undergone much change. In the death of Sir John Murray the organisation has suffered a great loss, but the genial and forceful personality of Dr. Johan Hjort is still an asset of much value. Prof. Otto Pettersson vacated the chair to Mr. H. G. Maurice, of the English Ministry of Agriculture and Fisheries, to whom the continued existence of the international investigations throughout the period of war is largely due.

ACCORDING to the *British Medical Journal*, Sir Frederick Banbury's Bill to Prohibit the Vivisection of Dogs is down for second reading on March 19. It will be remembered that when the same Bill was introduced last year a Government amendment allowing experiments to be made on dogs under special certificates was carried. The title was also changed. Sir Frederick Banbury himself moved the third reading with these amendments. The Bill was, however, rejected. It is now brought forward again in the form in which it existed before the Government amendments—that is, prohibiting all experiments on dogs. Although there seems some hope that the prospects of its progress in Parliament are not very favourable, its unexpected temporary success last year must not be forgotten, and careful watch is imperatively necessary. It is inconceivable that the Government can allow a Bill of this kind to pass, nullifying, as it does, the activities of so many of their Departments. Sir Frederick Banbury admitted that he had "failed to mention" the safeguards against possible cruelty already existing in the Statute Book. The opinion of the medical profession is sufficiently shown by the unanimous vote of the clinical and scientific meeting of the British Medical Association in London last April. It was agreed that such prohibition of experiments on dogs would have a deplorable effect in hampering the progress of physiological and pathological investigation, since many important fields of research are only available when dogs can be used. They are the only large animals that can be kept in health and comfort under laboratory conditions.

THE admission of qualified medical women to the fellowship of the Royal College of Surgeons of Edinburgh reminds us of the fight waged in the late sixties and early seventies of last century for the admission of women to the classes and examinations of the faculty of medicine of the University of Edinburgh. The fight was lost by the gallant band of women—*septem contra Edinem*. It has been fought and won in the fifty intervening years, and this resolution of the Royal College marks the fall of the last barrier to equality of the sexes in medical education in this ancient seat of learning. Women medical students have recently been admitted to the complete courses in the faculty of medicine, and the extra-mural Edinburgh School of Medicine for Women has been merged into the University. It remains to be seen whether the new *régime* will justify those who have borne much anxiety and labour to promote it. We believe it will. The Scottish women proved their quality in the hospitals they equipped and staffed in the various seats of war. They have started a small hospital in Edinburgh staffed by women only. There is an increasing body of medical women and women students attached to the University, and among them will be found doubtless the same capacity for work and leadership which was so nobly exemplified by the late Dr. Elsie Inglis. With all the examinations open to women which lead to hospital staff appointments, it is hoped that an increasing number of highly qualified women will present themselves as candidates when vacancies occur, and that appointments will be open to merit irrespective of sex. Much of the work to be done in the future in the State-aided hospital is obviously of a character to

demand the services and judgment of qualified medical women.

THE twenty-sixth James Forrest lecture will be delivered at the Institution of Civil Engineers on Tuesday, April 20, at 5.30 p.m., by Sir Dugald Clerk, K.B.E., F.R.S., upon the subject of "Fuel Conservation in the United Kingdom."

PROF. A. FOWLER, professor of astrophysics, Imperial College of Science and Technology, South Kensington, and president of the Royal Astronomical Society, has been elected a corresponding member of the Paris Academy of Sciences, in the section of astronomy, in succession to the late Prof. E. Weiss, of Vienna.

PROF. J. STANLEY GARDINER has, at the request of the Deputy-Minister of Fisheries, undertaken temporarily the direction of the scientific work of the Fisheries Department of the Ministry of Agriculture and Fisheries. Prof. Gardiner's particular duty will be to restart fishery investigations, which have necessarily been in abeyance during the war.

THE Faraday Society has arranged a general discussion on "Basic Slags: Their Production and Utilisation in Agricultural and other Industries," to be held on Tuesday, March 23, from 7.30 to 10.30, in the rooms of the Chemical Society, Burlington House, London, W.1. Prof. F. G. Donnan, vice-president, will preside over the discussion, and there will be papers by Dr. E. J. Russell, Prof. C. H. Desch, Sir T. H. Middleton, Sir Daniel Hall, Prof. D. A. Gilchrist, and others.

THE U.S. National Research Council has received a gift from the Southern Pine Association of 10,000 dollars to meet the incidental expenses of a co-ordinated scientific study by a number of investigators of the regrowth of trees on cut-over forest-lands, with the view of determining the best forestry methods for obtaining the highest productivity. The investigation will be conducted under the advice of the Research Council's special committee on forestry, and will not duplicate any present Government or other undertakings along similar lines.

IT was announced at the ordinary scientific meeting of the Chemical Society on March 4 that the following had been proposed for election as honorary and foreign members, and that a ballot for their election would be held on March 18: W. D. Bancroft, V. Grignard, H. Kamerlingh Onnes, E. Paterno, P. Sabatier, J. B. Senderens, S. P. L. Sörensen, and G. Urbain. The annual general meeting of the society will be held at Burlington House on Thursday, March 25, at 5 p.m., to receive the address of the president, Sir James J. Dobbie, and to elect the officers and council for the ensuing year.

THE following officers and council of the Geological Society have been elected for the ensuing year:—*President:* R. D. Oldham. *Vice-Presidents:* Prof. E. J. Garwood, G. W. Lamplugh, Col. H. G. Lyons, and Prof. J. E. Marr. *Secretaries:* Dr. H. H. Thomas and Dr. H. Lapworth. *Foreign Secretary:* Sir Archibald Geikie. *Treasurer:* Dr. J. V. Elsden. *Other Members of Council:* Dr. F. A. Bather, Prof. W. S. Boulton, R. G. Carruthers, Dr. A. M. Davies, J. F. N. Green, R. S. Herries, J. Allen Howe, Prof. O. T. Jones, Prof. P. F. Kendall, W. B. R. King, Dr. G. T. Prior, W. C. Smith, Prof. H. H. Swinnerton, and Prof. W. W. Watts.

THE first of the Chadwick public lectures on military hygiene was delivered by Gen. Sir John Goodwin, Director, Army Medical Service, on March 8 at the Royal Society of Arts, the subject being "Army Hygiene Prior to the Recent War." The lecturer dealt with the history of hygiene from the earliest times up to the period immediately preceding the war. The ravages wrought by disease during the various campaigns of the eighteenth and nineteenth centuries and their effects upon the armies in the field were detailed, and emphasis was laid on the lessons gained during the South African War in the prevention of disease. The various measures that have been elaborated to improve the health of the Army were outlined, and stress was laid on the good results accruing from education in hygiene of the Army as a whole. In India, during the years 1878–82, the number constantly sick among the European troops was 68·1 per 1000, with a mortality of 20·5; in 1912 the corresponding figures were 28·8 and 4·6 respectively. Immediately preceding the lecture Chadwick gold medals and prizes were presented to Surg.-Comdr. Edward L. Atkinson, R.N., and Brig.-Gen. W. W. O. Beveridge, A.M.S., for services in promoting the health of the men of the Navy and Army.

WE are authorised to announce that H.R.H. the Prince of Wales has been graciously pleased to become the patron of the new British School of Archæology in Jerusalem, referred to in NATURE of December 18 last (p. 398). The school has been formed for the study of the wide and important field of archæological research which has now been opened up in Palestine and the surrounding districts. The director, Prof. J. Garstang, of the University of Liverpool, is shortly proceeding to Palestine to complete the organisation of the school. As soon as the political destiny of Palestine has been fixed and a mandate formally assigned, it is hoped that a department of antiquities will be formed, under which the school looks forward to collaborating with the Palestine Exploration Fund in the excavation of an important site which has already been provisionally selected. Anyone who is interested in the school is invited to communicate with the secretary at 2 Hinde Street, Manchester Square, W.1.

THE Natural History Museum Staff Association opened its series of scientific reunions for the current year by holding a double reunion on March 2 and 3. At the first most of the members of the International Council for the Exploration of the Sea were present, and the exhibits arranged in the board-room included many specimens—some being classical type-specimens—collected during the voyage of the *Challenger*. At the second reunion other exhibits were added, so that the whole series was of wide interest, and there was an attendance of nearly fifty visitors, amongst whom may

be mentioned Lord Rothschild, Sir Ronald Ross, Prof. E. B. Poulton, Lt.-Col. Winn Sampson, Mr. F. E. Beddard, Prof. J. Stephenson, Dr. H. O. Forbes, Mr. R. F. Scharff, Prof. J. P. Hill, Dr. S. Kemp, Dr. B. Daydon Jackson, Prof. J. Graham Kerr, Mr. S. Monckton Copeman, Mr. G. T. Bethune Baker, Dr. E. J. Allen, Dr. H. H. Thomas, Dr. C. Christy, and Prof. J. E. Duerden.

The half-yearly council meeting of the National Union of Scientific Workers, presided over by Mr. G. S. Baker, of the National Physical Laboratory, was held at University College on March 6. The rapid growth of the union has necessitated the appointment of a full-time secretary, and Major A. G. Church has been appointed to fill that office. The research committee in its report outlined the function of this body and that of the research council, which it is hoped will shortly be constituted. It will consider how best industry and public administration should be kept in close touch with the development of scientific knowledge, and ensure that the views and conditions of employment of scientific workers shall receive consideration from all bodies bringing forward schemes for research in science or for the administration of research. It was felt that the State should not subsidise industrial research associations unless such bodies display an anxiety to ensure that the direction of research shall be in the hands of those who have shown capacity for leadership in scientific work. A report on patent rights presented by Mr. A. A. Griffith emphasised the opinion "that the only satisfactory way of remunerating salaried inventors is to pay them adequate salaries; a salaried inventor receiving an adequate salary should have no claim whatever to any extra payment because his work proves unexpectedly remunerative." On the motion of Miss A. B. Dale, the council unanimously agreed to "protest strongly against the differential treatment of men and women as regards the method of recruitment to the Civil Service and the salary scales offered therein as recommended by the Reorganisation Sub-Committee of the Civil Service National Whitley Council."

February was unusually warm over the southern portion of the British Isles, and at Greenwich Observatory the mean temperature for the month was 43·9°, which is 4° above the normal; the mean, however, was higher in 1914, when it was 44·9°, and the means of both maxima and minima readings were also higher. There were four days with a shade temperature of 60° or above, whilst there is no previous February at Greenwich with more than two such warm days since 1841, and in all only seven days as warm during a period of seventy-nine years. Frost in the shade only occurred on four nights during the month, and the lowest temperature was 27°. The duration of bright sunshine was eighty-seven hours, which is thirty hours more than the normal, and there were three days at Greenwich with eight hours and more of sunshine. Rainfall was much below the normal, and in London there was no day during the month with a fall of 0·1 in.; the total measurement was 0·39 in., which is the driest February since 1895 and 1896. Rain was measured only on eight days. The whole winter, December, January, and February, has been unusually mild over England, and at Greenwich the mean temperature for the three months was 42·8°, which is 3·5° warmer than the average for sixty years. The winter of 1915–16 was slightly warmer, and the winter of 1898–99 was warmer by about 1°. The warmest winter during the last eighty years, 1868–69, was warmer than the winter just ended by nearly 2°.

In view of the prevalence of disease amongst honey-bees during recent years, it has become a matter of practical importance to be able to distinguish with certainty between individuals which have died from disease and those the death of which is merely the result of old age or exhaustion. Mrs. Pixell-Goodrich contributes an interesting paper on this subject to the *Quarterly Journal of Microscopical Science* (vol. lxiv., part 2). It appears that during the summer, when actively engaged in collecting honey and pollen, the worker-bees very soon wear themselves out and die a natural death at the age of about six weeks. Senescence—or perhaps one should rather say exhaustion from over-exertion—is accompanied by well-marked and easily recognisable changes in the nerve-cells of the "brain." The cytoplasm of these cells undergoes gradual reduction in quantity, until only a vestige remains around the nucleus. The examination of the nerve-cells appears to be the most trustworthy method yet proposed for determining the age of bees, but, unfortunately, it involves a considerable amount of labour in the case of each individual examined.

The Bulletin of the Bureau of Standards for July 12, 1919, contains the results of the measurements of the index of refraction of air for wavelengths 2000 to 10,000 tenth metres at different temperatures and pressures made by Messrs. W. F. Meggers and C. G. Peters to meet the demands of modern accurate spectroscopy. The Fabry and Perot interferometer was used in the measurements, the plates being of glass or quartz 4·2 cm. in diameter and 0·6 to 0·8 cm. thick. They were rendered partially reflecting by films spluttered from a metallic cathode *in vacuo*. Iron or copper arcs and neon or argon tubes served as sources of light. The interference rings were photographed and the diameters of the first three measured. Between the limits of pressure used—73 to 76 cm.—the refractive index was found proportional to the pressure. The variation of the index with temperature between 0° C. and 30° C. is not sufficiently well represented by the usual $\mu - 1$ proportional to density law. The index of refraction at normal temperature and pressure is given by the equation $\mu^2 - 1 = \frac{0.0005738\lambda^2}{\lambda^2 - 595260}$, which shows no sign of an appreciable absorption band in the infra-red part of the spectrum.

The annual report of the Institution of Mechanical Engineers gives particulars of the various researches which are being carried on under the direction of the institution. The following grants were made by

the council for the year:—Alloys, 220*l.*; steam-nozzles, 150*l.*; hardness tests, 150*l.*; and cutting tools, 100*l.* The alloys research has been carried on at the National Physical Laboratory, and the eleventh report will be presented at an early date. The construction of the experimental apparatus for the steam-nozzles research has been further delay for lack of funds, but help has been promised by a grant of 500*l.* from the Turbine Blade Research Committee of the British Electrical and Allied Manufacturers' Association. It is intended to erect the apparatus at the Dickinson Street Power Station, Manchester, and the experiments will be conducted under the supervision of Prof. G. Gerald Stoney and Mr. S. L. Pearce. Hardness tests have been carried out at the National Physical Laboratory by Dr. T. E. Stanton, and it is hoped that reports will be presented this year. A bibliography on cutting tools is being prepared by Mr. G. W. Burley, and it is proposed to collect information from makers and users of cutting tools. The work of the wire-ropes research committee has been considerably delayed owing to the war; arrangements have now been made for experimental work to be carried out at Woolwich Polytechnic by Dr. W. A. Scoble. The work of the refrigeration research committee has been suspended since 1914; it is hoped that investigations may be made shortly into the physical properties of the substances used in refrigeration.

A CATALOGUE (No. 357) of rare books and manuscripts has just been issued by *Messrs. Bernard Quaritch, Ltd.*, 11 Grafton Street, W.1, and is worthy of perusal. It is of a fairly general character as to the subjects, but two sections will appeal especially to readers of NATURE, viz. those dealing with natural and physical sciences (21 pp.) and with periodicals (13 pp.). Many scarce volumes and long runs are to be found in these. The price of the catalogue is 1*s.* We notice that Messrs. Quaritch are about to begin the publication of the *Journal of Pomology*. It will appear at quarterly intervals under the editorship of Mr. E. A. Bunyard, who has secured the promise of assistance from many experts.

AN illustrated book on "Weeds of Farm Land," the work of Dr. Winifred E. Brenchley, of the Rothamsted Experimental Station, is to be published by *Messrs. Longmans and Co.* It will deal with various aspects of the weed problem, but especially with the relations existing between weeds and the soils and crops with which they are chiefly associated. A survey will be given in the volume of the present position with regard to the questions of prevention, eradication, and uses of weeds, also of their habits and method of distribution and the vitality of buried weed-seeds.

READERS of NATURE who are interested in ancient herbals and old-time gardening and agriculture should see Catalogue No. 81 of *Messrs. Dulau and Co., Ltd.*, 34 Margaret Street, W.1, in which are to be found particulars of 1000 works dealing with these and other scientific subjects, many the property of the late Sir Frank Crisp. An unusual feature is a collection of volumes on sundials.

Our Astronomical Column.

BRIGHT METEORS.—A fine meteor was observed on February 17 at 8h. 52m. by Mr. F. Wilson, Totteridge, and Mr. S. B. Mattey, Plumstead. It was brighter than Jupiter, and moved very slowly from a radiant at $72^{\circ}+43^{\circ}$ near α Aurigæ. The approximate height of the object was 67 to 30 miles, path 53 miles, and velocity 10 miles per second. It passed from over south-west of Needham Market to Woodbridge.

Another very brilliant meteor was observed on February 27 at 8h. 58m. by Mrs. Wilson and Miss Cook, and also by Mr. S. B. Mattey at Plumstead. The radiant was at about $17^{\circ}+8^{\circ}$ near the horizon 9° north of west. The height of the object was 53 to 49 miles, path 95 miles, and velocity 12 miles per second. It passed from over Lydd, Kent, to about 50 miles east of Calais, France. Fireballs from Auriga and Pisces have been recorded in previous years at about the same dates as those of this year.

TOTAL LIGHT OF THE STARS.—The late Prof. Newcomb laid stress on the desirability of obtaining this observational constant, and several attempts have been made to do so. The latest is by Mr. P. J. Van Rhijn (Contributions from Mount Wilson Observatory, No. 173). This paper shows that there is illumination, which is probably due to (*a*) a faint extension of the zodiacal light, including the Gegenschein, and (*b*) faint auroræ. The amount of these was found by observing regions of the sky remote from the Galaxy and assuming that the starlight in these regions could be inferred from the observed number of stars of each order of magnitude. The amount of each of these is discussed, and it is concluded that the total amount of light received from all the stars in both hemispheres is equal to 1440 stars of magnitude 1·00, Harvard visual scale. The following are the values of extra-galactic sky brightness per square degree found by different observers, the unit being a star of magnitude 1·00:—Newcomb, 0·029; Burns, 0·050; Abbot, 0·075; Yntema, 0·140; and Van Rhijn, 0·130. The magnitude of the full moon is about -12; it is, therefore, about 140,000 times as bright as a star of magnitude 1·00, or a hundred times as bright as all the stars together.

STAR CLUSTERS.—*Scientia* for March contains the fourth of a series of papers on clusters by Dr. Harlow Shapley. Dr. Shapley quotes a remark that distance introduces simplification in our study of the clusters; it makes apparent magnitudes equivalent to absolute ones, since all the components are at practically the same distance from us. He then proceeds to consider the local cluster to which the sun belongs, which he regards as defined by Dr. Charlier's research on the distribution of the B stars in space. The conclusion was that they form a flattened cluster, with greatest diameter 4000 light-years. This is supposed to be merely one unit out of many that go to make up the galaxy. Its equatorial region is marked by a zone of bright stars, to which attention was directed by Sir J. Herschel and Dr. B. A. Gould. Its plane is inclined some 15° to the medial line of the galaxy. Dr. Charlier puts the centre of the local cluster in Carina, some 250 light-years from the sun; while Dr. Shapley makes the distance only 150 light-years.

Since from analogy the cluster is likely to be moving with respect to its neighbours, the two star-drifts would appertain respectively to cluster and non-cluster stars. It is left an open question to which category the sun belongs. Viewed telescopically from the Hercules cluster, the local cluster would seem to be mainly composed of B stars, with a smaller number of giant M ones. The sun would be of the twentieth magnitude, too faint for visual observation, though it might be photographed.

Meteorological Observations at Calcutta.[1]

THERE is a perpetual struggle between the advocates of continuity and of uniformity in such matters as meteorological observations. For a network of official stations under a central authority, the results of which have to be co-ordinated, uniformity is of very great importance. On the other hand, experiments with different methods are much less likely to be discouraged in an independent observatory, the work of which has a value of a totally different kind. In such a place continuity has a special significance, and it is refreshing to meet with a volume of data from a station that has been on the same site for fifty years, even though that site was criticised very soon after the beginning of the period.

The official observatory at Alipore is only two miles from St. Xavier's College, so that the latter is not required as a vital station for the Indian Meteorological Service, and the Jesuit Fathers, who have maintained their observatory for half a century, have received no special blame for departures from established practice, or any financial support. The Rev. E. Francotte, S.J., has been director for thirty-two years out of the fifty, and is responsible for the present volume of some 350 pages of very clear print with large figures not at all crowded. His full plan consists of four parts, of which the volume before us is the first. It contains for each day in the fifty years, 1868–1917, maximum, minimum, and mean shade temperature, with maximum solar radiation and minimum terrestrial radiation, barometric pressure, wind direction and velocity, relative humidity and rainfall; the monthly extremes in heavy type, with notes on absolute extremes where encountered. This is intended to show the mutual relations of climatic elements, and to further this object, in addition to the tables, some graphs are added. The original scheme was to publish at the end of forty-six years, and part of the volume is summarised for that period. The war, which held back publication, enabled four more years to be included in an appendix.

We have not space to consider in any detail the mass of data contained in the volume, but a few points of interest may be mentioned. In forty-six years the average number of days with at least 1 in. of rain was nineteen per annum. Daily falls of at least 10 in. occurred five times in the period, including one total fall of 14 in. The shade temperature reached 100° F. on 527 days in forty-eight years: 59 in March, 282 in April, 136 in May, 48 in June, and only 2 in July, both in 1897. Father Francotte examines some of the tables for periodicity, but is reserving a great deal more analysis for the second volume, the publication of which will be awaited with interest by those who have seen the first.

W. W. B.

The Road to Industrial Peace.[2]

FROM time to time the Advisory Council of Science and Industry in the Australian Commonwealth issues bulletins dealing with various industrial problems, and the latest of its publications is entitled "Welfare Work," though it is wider in scope than the title is usually taken to imply. The preface tells us that the bulletin is prepared for the benefit of all who are seeking for some road to industrial peace and the establishment of more satisfactory and harmonious relations between capital and labour. It points out that these relations are far wider than questions of wages and hours of labour. A comprehensive industrial policy considers the responsibilities which fall on the shoulders of employers, the effect of industrial conditions on the employee, his well-being outside working hours, the distribution of the wealth produced, and the participation of the employees in the management and control of industrial operations. The bulletin sets out what has been done on these lines in Great Britain, the United States, and other countries, and in order to encourage its circulation it is issued at a very low price. It is to be hoped that it will receive the wide publicity it deserves, not only in Australia, but in this country as well. It is, in fact, of more direct interest to us than to its country of issue, in that all reference to welfare work in Australia is reserved for publication in a later bulletin.

The bulletin is admirably written, and affords a most valuable and impartial summary, especially of the large body of information which has been acquired during the war through the activity of the Health of Munition Workers Committee and other bodies. It describes the motives, scope, and administration of welfare work, and the social life, recreation, education, and housing of the workers. It discusses wage-payments, profit-sharing and co-partnership, provision for old age and sickness, and it goes somewhat fully into what is being more and more recognised as the most important factor of all in the attainment of industrial peace, viz. co-operation between employers and employed in control. The health and safety of the worker and the provision of a healthy industrial environment are debated at some length, whilst there is an excellent summary of problems of industrial fatigue in relation to hours of labour, overtime, and rest pauses. An extensive bibliography is included.

H. M. V.

Wireless Telephony in Aeroplanes.

IN a paper read before the Wireless Section of the Institution of Electrical Engineers on February 18 Major C. E. Prince lifted the veil from the important results in wireless telephony from aeroplanes which were achieved in consequence of the stimulus of the necessities of war. Up to the summer of 1915, the author believes, wireless speech had not been received in an aeroplane, and, indeed, great were the difficulties that had to be surmounted before practical apparatus for working between ground and aeroplane or between aeroplane and aeroplane could be produced. In the earlier experiments, transmission from air to ground only was attempted by a small oscillation-valve set, but an aeroplane-carried receiving set, also of the oscillation-valve type, was successfully used in 1916. This, however, did not meet the immediate military requirements overseas, and attention was more particularly devoted to the urgent, but more difficult, problem of telephonic communication between machines in the air.

Major Prince gave a good idea of the difficulties encountered and the ingenuity with which he and his colleagues surmounted them. The crux of the problem is the method of controlling the radiation. Direct control was found to suffer from grave disadvantages. Placing a microphone in the grid circuit of the oscillation valve was tried with some success, but finally a method known as "choke" control, in which the modulation is applied to the anode circuit of a second or control valve, was employed. The grid of the control valve is acted on by the microphone transformer, the anode of which is in series with a one-to-one transformer, or choke coil, in the

1 "Meteorological Observations at St. Xavier's College, Calcutta. (With a Short, Cursory Discussion on the Same)." Part I., Forty-six Years, 1868–1913. With Appendix, 1914–17. By E. Francotte. Pp. xiv+359. (Calcutta: St. Xavier's College, 1918.) Price, unbound, Rs. 3 per copy.

2 "Welfare Work." Bulletin No. 15 of the Advisory Council of Science and Industry. (Melbourne, 1919.) Pp. 110. Price 6d.

anode circuit of the main valve. When variations take place in the control anode at speech frequency, very large surges are set up in that of the power valve, which may approximate to the original high-tension direct-current potential, and so sweep the output from nearly double its steady value to zero. The standard R.A.F. set is of the 20-watt size, with a high-tension supply of 600 volts direct current. A great advantage in the system for aeroplane work is that no critical adjustments are required. The arrangement of the apparatus is such that the set proper can be mounted in any convenient position, and only a very small control unit brought within reach of the user's hand. One switch makes or breaks the dynamo field, filament, and microphone circuits. A great deal of experiment was necessary before a suitable microphone was found, as it had to be almost insensible to sounds of "noise" intensity, but responsive to the powerful concentrated waves of a voice impinging upon it at a very short distance.

The receiving set depended upon high-frequency magnification, and was, in its first form, a three-valve arrangement. It consisted essentially of a detector valve with reaction and two note magnifications. The detector valve was not energised direct from the aerial, but through an aperiodic circuit, which was a circuit approximately syntonised by its self-capacity. The final adjustment for obtaining the best effect is made on a rheostat in the filament circuit carried on the "joystick" itself. These three-valve sets were employed to a considerable extent both before and after the armistice, but a five-valve receiver was developed later in which a choice was made of two high-frequency magnifications and two low, with a detector valve. This set was very much more sensitive than the three-valve arrangement, and enabled fixed aerials rigidly connected to the wings and fuselage to replace the trailing aerial, which latter was a great embarrassment in fighting. The normal safe range of the apparatus is about four miles from machine to machine, while the range to a ground station is from twenty to fifty miles or more. The author anticipates that in the future the wireless apparatus will be able to be plugged through on to the ordinary exchange lines, so that a man sitting in his office will be able to hold a conversation with a machine in the air.

Magnetic Storm of March 4-5.

THE Director of the Meteorological Office has been good enough to send us the subjoined communication from Dr. Chree concerning a magnetic storm which occurred on March 4 and 5. It may be mentioned that on these days the sky was mostly overcast in Scotland, though there was very fine weather in the South of England. We are informed that the only aurora observation reported so far was made at Aberdeen at 1h. 30m. on March 4, *i.e.* ten hours before the "sudden commencement" of the storm:—

"A considerable magnetic disturbance was recorded at Kew Observatory on the night of March 4-5.

"There was a well-marked S.C. (sudden commencement) at about 11h. 40m. on March 4. This was of an oscillatory character both in D (declination) and H (horizontal force). The first, smaller, movement was a fall in H and an easterly swing in D, the range of the oscillation being about 45 γ in H and 7′ in D. H retained an enhanced value for four or five hours after the S.C., and no really large movements occurred until after 17h. on March 4. The most disturbed time was from 18h. on March 4 to 0h. on March 5. On the whole, H was falling from 17h. on March 4 until after 2h. on March 5, the maximum being recorded at about 16h. 20m. on March 4, the minimum at about 2h. 5m. on March 5, and the range being approximately 300 γ. The H curve had become quiet before 10h. on March 5, but still showed a depression of about 75 γ.

"The D trace was off the sheet, in the direction answering to easterly displacement, for fully twenty minutes between 22h. and 23h. on March 4; so the range recorded, 60′, may have been considerably exceeded. The maximum westerly displacement occurred at about 18h. 35m. on March 4.

"From 12½h. to 17½h. on March 4 the D trace was practically normal except that the declination was 1′ or 2′ more westerly than usual. Thus the disturbance was rather a conspicuous example of the lull that not infrequently intervenes between the S.C. and movements that would be recognised as constituting a magnetic storm."

University and Educational Intelligence.

CAMBRIDGE.—Mr. E. V. Appleton, of St. John's College, has been appointed an assistant demonstrator in experimental physics.

It is proposed to confer the honorary degree of D.Litt. on the Abbé Henri Breuil, professor of the Institute of Human Palæontology at Paris.

It is proposed to create a readership in the morphology of vertebrates and a lectureship in zoology in place of the present readership in zoology.

Besides additions and improvements to the chemical laboratory and the erection of the Molteno Institute for Parasitology, other building schemes are in view for engineering, physics, and also for the University library. The last proposal to meet the difficulty of finding room for books was to excavate a large underground chamber. The cost of this has been found to be prohibitive, and the Senate has recently discussed a revival of an old scheme to erect a new building akin to the Senate House and on the south side of Senate House Yard. If this scheme is adopted a public appeal will be made for subscriptions towards the erection of the building.

LEEDS.—Mr. W. E. H. Berwick has been appointed lecturer in mathematics in the University. Mr. Berwick was assistant lecturer in the University of Bristol for two years, and afterwards became lecturer in mathematics in University College, Bangor. For two years he was engaged on the technical staff of the Anti-Aircraft Experimental Section of the Munitions Inventions Department at Portsmouth, where he made important contributions to the experimental and computative theory of gunnery. He has published a long series of papers in the Proceedings of the London Mathematical Society and elsewhere.

OXFORD.—Prof. R. A. Sampson, Astronomer Royal for Scotland, has been appointed Halley lecturer for 1920.

THE governors and trustees of Tancred's studentships propose to elect a student in physic at Gonville and Caius College, Cambridge, at Whitsuntide. The annual value of the studentship is about 95*l*. Particulars are obtainable from Mr. E. T. Gurdon, 28 Lincoln's Inn Fields, W.C.2.

THE sixth annual report of the Carnegie United Kingdom Trust is an account of the work done by the Trust in 1919, and contains a statement of income and expenditure for the year. The committee had hoped that the coming of peace would have brought with it a great opportunity for institutions which

exist for philanthropic purposes. But the first year of peace has been a disappointment. Building operations, which form a very large part of the activities assisted by the Trust, are kept back because building is now so costly. The outstanding obligations already undertaken by the Trust are sufficient to absorb the greater part of the available income during the next five years. It is evident that further sums will be required to supplement grants already made for building libraries. The committee is, therefore, disinclined to consider new requests for grants in aid of library building. The committee considers that the assistance given to rural library schemes is among the most important and satisfactory of the Trust's activities. Under these schemes a box containing fifty books is sent to a small town or village and there used as a lending library until, the books having been read, it is time to exchange them for a fresh supply. Reports from those in charge of rural centres show that the scheme really provides a means for spreading education in thinly populated districts. The Carnegie Trust has made a grant towards the maintenance of the School of Librarianship recently established at University College, London. The highly trained students who pass through this school should do much to make our libraries more useful. The committee of the Carnegie Trust also reports on the part it has taken in physical welfare schemes and in the promotion of music.

AN appeal has just been issued by the University of London through its Military Education Committee inviting subscriptions to the war memorial which it is proposed to raise to the former officers and cadets of the University of London Officers Training Corps who have fallen in the war. The services rendered by the Officers Training Corps during the war are too little known or appreciated. When war broke out the cadets came forward practically as one man, and to their heroism and the unremitting labours (often in the teeth of great discouragement and difficulties) of their pre-war instructors we owe the fact that what might have proved a most dangerous gap in the supply of officers during the earlier part of the war was successfully bridged. The record of the University of London contingent appears to be second to none. The number of past and present officers and cadets who served in the war as officers is 4197, of whom we have to deplore the loss of no fewer than 657. The number of distinctions gained is 1650, including five V.C.'s (the only two surviving V.C.'s, Major Cloutman and Major White, both graduates of the University, are honorary secretaries of the appeal). In particular the gratitude of Londoners must go out to Major Sowrey, who brought down a Zeppelin in flames, and later a Gotha aeroplane. The scheme is to include a memorial in London, and, in addition, a permanent hall in connection with the new standing camp of the University of London O.T.C. at Great Kimble, near Princes Risborough, where special memorials to individuals may be put up, of which the first will commemorate Lt.-Col. Arthur Egerton, Coldstream Guards, the first adjutant of the contingent, whom all the original officers and cadets mourn as a personal friend. The appeal committee is a strong one, and includes many honoured names outside the University itself—in particular, those of Marshal Foch and of Field-Marshals Lord French and Sir Henry Wilson. It is to be hoped that every patriotic person who realises the part played by the British universities in the great national struggle and the importance of maintaining this splendid tradition will contribute generously towards the 30,000*l.* asked for. Contributions should be sent to the hon. treasurer at 46 Russell Square, London, W.C.1.

Societies and Academies.

LONDON.

Royal Society, February 26.—Sir J. J. Thomson, president, in the chair.—L. F. **Richardson**: Some measurements of atmospheric turbulence. The eddy-shearing stress on the ground is deduced from pilot-balloon observations. Values on land in any consistent dynamical units are found to range from 0·0007 to 0·007 times the value of m^2/ρ, where m is the mean momentum per volume up to a height of 2 km. and ρ is the density. Evidence is given to show that the eddy viscosity across the wind at Lindenberg increases with height, and, except near the ground, is much greater than the eddy viscosity along the wind. In parts iv. and v. the spreading of a lamina of smoke is considered. Osborne Reynolds's eddy stresses are studied. For one occasion an attempt was made to measure simultaneously all six components of stress by observing the motion of thistledown. The three direct stresses are easily measured. Not so the shearing stresses; however, one was found to be 2·4 times its probable error. The theory of the scattering of particles is summarised, and numerical values are derived from scattering. The "turbulivity" ξ is estimated from the rising cumuli in calm weather and found to be 10^6, applicable only in the sense of friction. Thus the whole range of ξ observed in the free atmosphere was from seven to a million, in contrast with 0·2 in perfectly still air. The eddy stresses observed have ranged in absolute value from 0·004 to 110 dynes cm^{-2}.—J. H. **Hyde**: The viscosities and compressibilities of liquids at high pressure. In the first place, experiments were made to determine the change in the value of the kinematical viscosity (η/ρ) of the various oils, and after this investigation was completed apparatus was designed for the determination of the change in density with pressure. The apparatus used for the determination of the kinematical viscosity consisted essentially of a system of two horizontal (the upper one of capillary dimensions) and two vertical tubes forming a closed circuit of liquor under pressure, the lower half of the circuit containing mercury and the upper half the liquid under test. One end of the tubular frame rests on a horizontal knife-edge, and the frame is supported in a horizontal position by a spiral spring. On the mercury being displaced by a given amount, flow will take place round the circuit owing to the difference of head, and it is evident that if the spring be so designed that its rate of extension is equal to the rate of change of head of the mercury, flow of the liquid under test will take place through the capillary tube under a constant pressure-difference and at a velocity which can be calculated from the rate of extension of the spring. In this way all the data required for the determination of the absolute kinematic viscosity of the fluid were determined. The determinations of the variation in density under pressure were made by measuring the decrease in volume of known quantity of the liquid enclosed in a steel cylinder sealed at one end and closed at the other by a long steel plunger. The cylinder and plunger were enclosed in a pressure vessel and the motion of the plunger for any particular pressure was measured. The density was calculated from the decrease in the volume thus measured. From the values of the density (ρ) and those of the kinematical viscosity (η/ρ) obtained for the oils, the values of the absolute viscosity (η) were calculated. The results show that the absolute viscosity of all the oils tested increases considerably with pressure.—A. **Russell**: The capacity coefficients of spherical conductors. It is proved that the capacity coefficient of a spherical

conductor equals its radius, together with the capacity of the condenser formed by the spherical surface on one side and the images in it of all external objects connected in parallel on the other. This theorem leads at once to relations between the capacity coefficients of a system of two spheres and the capacities of certain spherical condensers which lessens very appreciably the labour involved in computing the values of these coefficients which are required in practical work. The mutual coefficient also is given in terms of the capacity of a spherical condenser, and other relations between the various capacities used by engineers and physicists are proved. Finally, a method of finding the approximate value of the capacity between a sphere and distant large conductors is given.—C. **Cuthbertson** and Maude **Cuthbertson**: The refraction and dispersion of carbon dioxide, carbon monoxide, and methane. The refractivity of the above-named gases has been measured at eight points in the visible spectrum between $\lambda\lambda$ 6708–4800. The work was undertaken with the object of ascertaining the refractive power of the carbon atom, on the assumption of the validity of the additive law. By deducting the refractivity of the oxygen or hydrogen atoms from that of the carbon compound values are obtained from which the refractivity of carbon can be expressed in the form

$$\mu - 1 = \frac{C}{n_0^2 - n^2}.$$

For $n = 0$ the expressions obtained are:

	From carbon dioxide	Carbon monoxide	Methane
$(\mu - 1)_\infty =$ carbon	$\frac{2.7705}{16042} = 0.000173$	$\frac{1.988}{10213} = 0.000195$	$\frac{\text{—}}{10623}$

There are thus wide differences, not only between the quotients, which give the refractivity, but also between the numerators, which should be proportional to the number of "dispersion electrons," and the denominators, which give the squares of the hypothetical free frequencies. The result affords a further proof that the "additive law" is untrustworthy except as a rough guide.—A. A. **Griffith**: The phenomena of rupture and flow in solids. Difficulties which had been experienced in predicting the fracture of machine parts under certain types of loading suggested the desirability of a fundamental inquiry into the mechanism of rupture. A theoretical criterion of the rupture of an elastic solid, based on the "theorem of minimum energy," is enunciated in the paper. This has been shown experimentally to be true in the case of a glass plate which contains a crack when unstrained. The calculation involves the surface tension of the material. In the experiments the maximum stress in the glass was estimated to be more than ten times the normal tenacity of the material. It is shown that this result is compatible with the general criterion of rupture unless the material is weakened by discontinuities of flaws the dimensions of which are at least of the order ten thousand times the molecular spacing. Evidence is adduced to show that the strength of other substances, including metals and liquids, is governed by similar considerations, and that an enormous increase in the tenacity of materials would be possible if the flaws could be eliminated. Experiments are described showing how the elimination may be performed in the case of glass and fused silica, it having been found possible to prepare samples of these materials with nearly fifty times their normal tenacity. The strong phase of these materials is, however, unstable, and changes spontaneously in a few hours to the normal modification. It is shown that many of the phenomena associated with the mechanical properties of materials, including those described in the present paper, are capable of explanation in general terms if it be supposed that intermolecular attraction is a function of the relative orientation of the attracting molecules. Some consequences of this theory are discussed in the paper. The paper concludes with a short discussion of the bearing of the work on engineering practice.

Geological Society, February 20.—Mr. G. W. Lamplugh, president, in the chair.—Annual general meeting.—G. W. **Lamplugh**: Presidential address: Some features of the Pleistocene glaciation of England. The address dealt principally with the changes brought about by the ice in the surface-features of our country. More than five thousand square miles of English land, or about one-tenth of the whole country, would vanish if the drifts were removed, as the "solid" rocks lie below sea-level in tracts of this extent. A further area of about ten thousand square miles is overspread by drift of sufficient thickness wholly to mask the "solid" land-forms, so that rather more than one-quarter of the country owes its present shape to Glacial and post-Glacial deposits. Another twenty thousand square miles was glaciated, and more or less modified, but without losing the dominating features of its rocky framework. The remainder of the country was affected only by the intensification of the atmospheric agencies, whereby its original features were accentuated. In a general sense, the hill-districts have not been greatly changed, but the lowlands have been in most parts completely altered. The source of the huge mass of material contained in certain of the lowland drift-sheets was considered, and the opinion was expressed that a large portion of this was an addition to the land, brought in by the ice from outside our present coast-line. Comment was made on the curious rarity of peat or other land-detritus in Boulder Clay known to have been derived entirely from the land, and this was thought to indicate that the conditions for a long period before the actual glaciation had been unfavourable for the growth of timber or peat-producing vegetation.

February 25.—Mr. R. D. Oldham, president, in the chair.—H. C. **Sargent**: The Lower Carboniferous chert-formations of Derbyshire. The chert-formations occurring in the Carboniferous Limestone and associated rocks of Derbyshire may be classified under two heads: (1) Those which owe their silica to gaseous or aqueous emanations from igneous rocks. (2) Those which derived their silica from the land by means of chemical denudation. The author considers that in both cases the silica was precipitated direct, and did not, to any considerable extent, pass through an intermediate stage of secretion by organisms with subsequent solution and redeposition. He adduces evidence to show that simultaneous deposition of silica and calcium carbonate often took place, and it is believed that, in such cases, segregation ensued, and sometimes resulted in the formation of nodules and lenticular masses of chert. It is suggested that the bedded cherts of terrestrial origin resulted from heavier precipitation of silica, comparatively free from calcium carbonate, and spread over the sea-floor by gentle currents. Metasomatic replacement of limestone and calcareous organisms by silica has taken place at their contact with the chert. Impurities in the silica have tended to limit such replacement. Organisms existing in the sea or on the sea-floor would be entangled in the precipitated silica, and their presence in the chert is thus explained. The blackness of some chert is shown to be due to the presence of carbonaceous matter. Ferrous iron may possibly have operated sometimes in the same way.

PARIS.

Academy of Sciences, February 16.—M. Henri Deslandres in the chair.—G. **Humbert**: The positive quadratic forms of Hermite in an imaginary quadratic body.—M. **Hadamard**: Certain solutions of a functional differential equation.—G. **Bigourdan**: Co-ordinates, instruments, and work of the Observatory of the Collège de France.—A. **Rateau**: The greatest range and maximum realisable velocities of aeroplanes.—M. Diary of Societies.

THURSDAY, MARCH 11.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Lt.-Col. E. Gold: The Upper Air: (ii) Results and their Interpretation.

INSTITUTE OF METALS (at Institution of Mechanical Engineers) (Annual General Meeting), at 4.—Eng. Vice-Admiral Sir George Goodwin: Inaugural Address.

ROYAL SOCIETY, at 4.30.—W. G. Duffield, T. H. Burnham, and A. A. Davis: The Pressure upon the Poles of Metallic Arcs, including Alloys and Composite Arcs.—J. H. Vincent: Further Experiments on the Variation of Wave-length of the Oscillations Generated by an Ionic Valve Due to Changes in Filament Current.—H. A. Daynes: (1) The Theory of the Katharometer; (2) The Process of Diffusion through a Rubber Membrane.

LONDON MATHEMATICAL SOCIETY, at 5.—G. S. Le Beau: A Property of Polynomials whose Roots are Real.—B. M. Sen: Double Surfaces.

ROYAL COLLEGE OF PHYSICIANS, at 5.—Dr. J. L. Birley: The Principles of Medical Science as applied to Military Aviation (Goulstonian Lecture).

ROYAL INSTITUTE OF PUBLIC HEALTH, at 5.—Dr. H. M. Berry: X-rays in the Diagnosis of Tuberculosis.

ROYAL SOCIETY OF MEDICINE (Occasional Lecture), at 5.—Sir Jagadis Bose: Plant and Animal Response (with Demonstrations of Growth by the Magnetic Crescograph).

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. M. Jane Reaney: The Educational Needs of Adolescence.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—W. H. Patchell: Operating a By-product Producer-gas Plant for Power and Heating.—S. H. Fowles: Production of Power from Blast-furnace Gas.

OIL AND COLOUR CHEMISTS' ASSOCIATION (at 2 Furnival Street), at 7.—J. B. Shaw: Various Points in the Manufacture of Lake and Pigment Colours.

OPTICAL SOCIETY, at 7.30.—A. C. W. Aldis: Portable Electric Signalling Lamps.

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduate Section), at 8.—C. A. Chappell: Magnetos.

INSTITUTE OF METALS (at Institution of Mechanical Engineers) (Annual General Meeting), at 8.—Dr. G. D. Bengough, R. M. Jones, and Ruth Pirret: Fifth Report to the Corrosion Research Committee.—R. Seligman and P. Williams: The Action on Aluminium of Hard Industrial Waters.

ROYAL SOCIETY OF MEDICINE (Neurology Section), at 8.30.—Prof. J. S. B. Stopford: Results of End-to-end Suture of Peripheral Nerves.

SOCIETY OF ANTIQUARIES, at 8.30.

FRIDAY, MARCH 12.

INSTITUTE OF METALS (at Institution of Mechanical Engineers) (Annual General Meeting), at 10.30.—J. Neil MacLean: The Art of Casting in High Tensile Brass.—H. Moore and S. Beckinsale: The Removal of Internal Stress in 70:30 Brass by Low-temperature Annealing.—Dr. W. Rosenhain, J. L. Haughton, and Kathleen Bingham: Zinc Alloys with Aluminium and Copper.—Dr. W. Rosenhain: A Model for Representing the Constitution of Ternary Alloys.—A. C. Vivian: Tin-Phosphorus Alloys.—W. C. Hothersall and E. L. Rhead: Some Notes on the Effect of Hydrogen on Copper.

INSTITUTE OF METALS (at Institution of Mechanical Engineers) (Annual General Meeting), at 2.30.—W. E. Alkins: The Effect of Progressive Drawing upon some Physical Properties of Commercially Pure Copper.—F. Johnson: The Influence of Cold Rolling on the Physical Properties of Copper.—J. L. Haughton: The Study of Thermal Electro-motive Force as an Aid to the Investigation of the Constitution of Alloy Systems.—H. H. Hayes: The Polishing and Etching of Zinc for Micro-examination.—W. E. Hughes: Idiomorphic Crystals of Electro-deposited Copper.

ROYAL ASTRONOMICAL SOCIETY, at 5.—N. Liapin: Some Remarkable Properties of Diurnal Motion.—H. C. Plummer: The Nature of Short-period Variables.—L. Becker: (1) Capture Orbits; (2) The Capture Hypo-

thesis of Binary Stars.—T. C. Hudson: A Vectorial Theorem.—R. A. Sampson: Theory of the Four Great Satellites of Jupiter.—J. Jackson: The Orbits of 20 Double Stars.—H. W. Newton: Note on the Sun-spot and Facular Disturbance in the Region of the Eclipse Prominence of 1919.—A. S. Williams: The Observed Changes in the Colour of Jupiter's Equatorial Zone.—A. R. Hinks: A Preliminary Account of the Geography of the 1922 September 20 Eclipse Track.

PHYSICAL SOCIETY OF LONDON, at 5.—F. W. Newman: Absorption of Gases in a Discharge Tube.—F. S. G Thomas: A New Directional Hot-wire Anemometer of High Sensitivity, especially applicable to the Investigation of Slow Rates of Flow of Gases.—Dr. Hans Petterssen: Exhibit of a New Micro-balance.

UNIVERSITY COLLEGE ENGINEERING SOCIETY (Annual Public Meeting), at 5.30.—Sir Dugald Clerk: Coal Conservation.

MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—A. J H. Fitt and Others: Costing.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—F. A. Simpson: Chain Helice Pumps.

HARVEIAN SOCIETY (at the Medical Society of London), at 8.30.—Sir Thomas Horder: The Diagnostic Significance of Nerve Symptoms in Acute Infections (Harveian Oration).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—W. W. Rouse Ball: String Figures.

SATURDAY, MARCH 13.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir J. J. Thomson: Positive Rays.

MONDAY, MARCH 15.

VICTORIA INSTITUTE (at Central Hall, Westminster), at 4.30.—E. W. G Masterman: The Walls of Jerusalem at Various Periods.

ROYAL SOCIETY OF MEDICINE (Occasional Lecture), at 5.—Dr. J. Freeman: Toxic Idiopathies: The Relationship between Hay and other Pollen Fevers, Animal Asthmas, Food Idiosyncrasies, Bronchial and Spasmodic Asthmas, etc.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting) (at Chartered Institute of Patent Agents), at 7.—J. W. Beauchamp and S. M. Hills: Industrial Electric Heating.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—H. Austen Hall: The Planning of American Departmental Stores.

SURVEYORS' INSTITUTION, at 8.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Prof. J. L. Myres: The Dodekanese.

TUESDAY, MARCH 16.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Keith: British Ethnology—The Invaders of England.

ROYAL COLLEGE OF PHYSICIANS, at 5.—Dr. J. L. Birley: The Principles of Medical Science as applied to Military Aviation (Goulstonian Lecture).

ROYAL SOCIETY OF MEDICINE, at 5.—(Special General Meeting of Fellows.)

ROYAL STATISTICAL SOCIETY, at 5.15.—M. S. Birkett: The Iron and Steel Trades during the War.

INSTITUTION OF CIVIL ENGINEERS, at 5.30—Sir Alexander B. W. Kennedy; Lantern Exhibition of Views taken throughout the War Areas in France and Flanders.

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—M. A. Ockenden and A. Carter: Plant used in the Rotary System of Drilling Oil Wells.

MINERALOGICAL SOCIETY (at Geological Society), at 5.30.—A. Russell: The Occurrence of Cotunnite, Anglesite, Leadhillite, and Galena on Fused Lead from the Wreck of the Fireship *Firebrands*, Falmouth Harbour, Cornwall.—W. Campbell Smith: Riebeckite-rhyolite from Northern Kordofan.—Dr. G. T. Prior: The Meteoric Iron of Mount Ayliff, Griqualand East, South Africa.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—R. I. Pocock: The External Characters of South American Monkeys.—Dr. C. F. Sonntag: The Comparative Anatomy of the Tongues of the Mammalia: I. General Description of the Tongue.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Lantern Meeting), at 7.—Maj.-Gen. W. S. Brancker: Bird's-Eye Views of London and other Districts in England from Aeroplane Photographs.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—N. W. Thomas: The Ovia Secret Society (Illustrated by Lantern Slides and Phonograph Records).—Surg.-Lt. R. Buddle: Exhibition of Flint Implements from Russia.

WEDNESDAY, MARCH 17.

ROYAL UNITED SERVICE INSTITUTION, at 3.—Major H. F. S. Huntington The Physical and Ethical Value of Boxing.

ROYAL SOCIETY OF ARTS, at 4.30.—W. W. Beaumont: Street Passenger Transport of London.

ROYAL METEOROLOGICAL SOCIETY (at Royal Astronomical Society), at 5.—Capt. C. K. M. Douglas: Clouds as seen from an Aeroplane.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section) (at Institution of Civil Engineers), at 6.—Capt. P. P. Eckersley: Duplex Wireless Telephony: Some Experiments on its Application to Aircraft.

ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 8.—Major C. F. Abell: Airship Machinery.

ROYAL MICROSCOPICAL SOCIETY, at 8.

THURSDAY, MARCH 18.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Stephen Graham: The Spirit of America after the War.

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—W. B. Brierley: A Form of *Botrytis cinerea* with Colourless Sclerotia.—R. R. Gates: A Preliminary Account of the Meiotic Phenomena in the Pollen Mother Cells and Tapetum of Lettuce (*Lactuca sativa*).

LINNEAN SOCIETY, at 5.

ROYAL COLLEGE OF PHYSICIANS, at 5.—Sir John R. Bradford: The Clinical Experiences of a Physician during the Campaign in France and Flanders, 1914-1919 (Lumleian Lecture).

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—W. R. Jones: Tin and Tungsten Deposits: The Economic Significance of their Relative Temperatures of Formation.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Adjourned Discussion on the Papers of W. H. Patchell and S. H. Fowles read at the Meeting on March 11.

CHEMICAL SOCIETY, at 8.—I. Masson and R. McCall: The Viscosity of Nitrocellulose in Mixtures of Acetone and Water.—H. Stephen, W. F. Short and G. Gladding: The Introduction of the Chloromethyl Group into the Aromatic Nucleus.—H. E. Cox: The Influence of the Solvent on the Velocity of Reaction between certain Alkyl Iodides and Sodium β-Naphthoxide.—H. Crompton and P. L. Vanderstichele: The Use of 1:2-Dichlorovinylethyl Ether for the Production of Chloroacetates and Acid Chlorides.

FRIDAY, MARCH 19.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir William S. Meyer: The Indian Currency System and its Developments.

CONCRETE INSTITUTE, at 6.—Dr. O. Faber: The Practical Application of Reinforced Concrete.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—D. Brownlie: Exact Data on the Performance of Mechanical Stokers, as applied to "Lancashire" and other Narrow-flued Boilers.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—E. McCurdy: Leonardo da Vinci.

SATURDAY, MARCH 20.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir J. J. Thomson: Positive Rays.

PHYSIOLOGICAL SOCIETY (at University College), at 4.—J. F. Donegan and Others: Innervation of Veins.

the New Army.

THE memorandum of the Secretary of State for War relating to the Army Estimates for 1920–21, which has been recently issued by the War Office "in amplification of the speech of the Secretary of State introducing the Army Estimates" (Cmd. 565, price 3*d*.), is a notable document in both its national and scientific aspects. It represents the introduction of a new attitude towards military and medical science, as is shown by the following quotations:—

"We must continue to develop the power of our armaments, not by accumulating large stocks of weapons and stores for a great national Army in peace time of patterns that may become obsolete before they are used, but by scientific research and experiment which will lead to the design of the best types, and by preparation which will enable bulk production to commence without the unfortunate delays that had such a lamentable effect during the early stages of the Great War. . . . It is necessary to make adequate provision for research experiments and design in connection with war material. . . . We must, unfortunately, continue our studies of what is known as chemical warfare. . . . It is our policy to farm out to civil scientific institutions, such as the universities, the National Physical Laboratory, the Imperial College of Science and Technology, etc., all pure research that can be profitably farmed out, and, generally speaking, to restrict military institutions to applied research and the preliminary design of apparatus."

More could be quoted to encourage the belief that the Army has learnt its lesson, and, besides, there is the new Education Corps, as well as changes at Woolwich, Sandhurst, and the staff colleges, and new Army schools.

Those men of science who have served in the Army and were at times driven to despair by its patterns that have become obsolete in high places may be slow to believe in the seeming change of heart. With this memorandum before us, however, we are given reason for hope in improved conditions, and should assist in realising them. It is undeniable that, broadly speaking, early in the war, the Army was perilously out of touch and out of comprehension with respect to science, but it must also be remembered that the forces of science were not marshalled and led by any means so well as they might have been. The chemists, it is true, made an attempt to organise, but when they approached the Board of Trade with the view of establishing something like a clearing house, they succumbed to a strange *non sequitur* in the form of an assurance that the Government was going to establish a Department of Scientific and Industrial Research. Before and after that, chemists drifted to their various posts under a variety of currents, which only too often put a wrong man in a place for which the right one was equally available.

No doubt wonders were done, but it is surely most desirable that, for the future, science should have some scheme of mobilisation ready. In saying this, it is not suggested that a rigid scheme could, or should, be attempted, but there is something between detachment and regimentation that is better than either, and this at least it should not pass the wit of man to design.

Over-organisation is one of the reactionary extravagances of the war, and it is evident to some degree in the memorandum before us. Some pride appears to be taken for the provision of Co-ordinating Boards, which among other things "should lead to the detection of overlap [in research] where such exists, and its elimination." Overlap is the bogey of the official mind, and co-ordination the blessed word. So far as the advancement of science for peace or war is concerned, let us hope that philosophers will go to the stake rather than be deprived of their right to overlap anybody or anything they may choose.

The overlap of chemistry and physics is maintaining the credit of our country in science; an equal overlap of the General Staff of the Army and the brotherhood of science, if it can be achieved, will do also much for the safety of the country. That is the vital thing for which there is perhaps some promise, but not yet adequate assurance. Science linked to the Army by fussy research co-ordinators acting under a nescient soldier will not solve the difficulty. It is perhaps too much to expect that all officers on the General Staff will have had a scientific education, but until it is made obligatory for a proportion of them to have had such a training, the fundamental reform will not have been effected, and science will not occupy its rightful position in the new Army.

The section of the memorandum which relates to the Royal Army Medical Corps is of noteworthy interest. An important feature is the reorganisation of the medical section of the Territorial Army under the supervision of a Territorial section of the War Office. In view of the fine work which was done by Territorial units during the war, it is

to be hoped that this branch of the Medical Corps will be given the opportunities it deserves. The proposal to form a dental corps is indeed excellent, and it might be advantageous to unite with this the plastic surgery which was so intimately associated with dental work in the late war.

In our opinion one of the best changes in the Army medical administration is the establishment of the new directorates of pathology and hygiene; an important consequence of this is that promotion to the highest rank is now open to the specialists who take up such work in the Army. Efficient collaboration with the civil profession and with other branches of State medical work will be ensured by the aid of an advisory committee of experts, both civil and military. It may be assumed that the work hitherto carried on by the vaccine department of the Royal Army Medical College will henceforth be taken under the directorates of pathology and hygiene. The figures given in the memorandum show how largely the work of the vaccine department aided in maintaining the health of the troops in the field, and with a very much smaller expenditure than would have been entailed in private purchase. More than 33,000,000 doses of vaccines of various types were prepared during the last five years; the value of the vaccines is well illustrated by the case of the protection afforded against the typhoid group of diseases. In the French Army, before full protection against typhoid, there were from the outbreak of the war until the end of October, 1915, 95,809 cases, with 11,690 deaths; after the adoption of treatment the French figures were comparable with our own—during the entire war we had 7423 cases, with 266 deaths, in our Expeditionary Force in France.

The future of gas warfare is briefly dealt with in the memorandum. This form of offensive has evidently come to stay, and it is stated that, owing to the fact that preparations for the use of gas can be made in peace time with great secrecy, it is necessary continually to study defensive measures capable of meeting such a form of attack. Defence against gas involves physiological, quite as much as chemical, measures, as is shown by the important part played by physiologists in the elaboration of the British box respirator, which is the most perfect and wearable defence against all gases hitherto employed in war. It is to be hoped that the War Office will continue to consult both physiological and chemical experts in problems connected with the construction of respirators, and also in the arrangements for training troops in such devices.

The Roast Beef of Old England.

Cattle and the Future of Beef-Production in England. By K. J. J. Mackenzie. With a preface and chapter by Dr. F. H. A. Marshall. Pp. xi+168. (Cambridge: At the University Press, 1919.) Price 7*s*. 6*d*. net.

WITH the advent of peace, British agriculture, still harassed and bewildered by the vagaries of a "control," painful, like a tooth, in its going as in its coming, has entered upon a transition stage towards the establishment of a new equilibrium, the character of which must be a subject of anxious concern to all who believe that a prosperous and contented agriculture is the soundest basis upon which the national welfare can rest. At this juncture wise counsel is needed from those best qualified to give it, and it will find a more sympathetic hearing than was wont to be the case in the bygone days when farming was so generally looked upon more as a mode of life than as a complex industry of vital importance to the nation, and requiring the sympathetic and active support of the community.

The change in the direction of an increase of plough-land at the expense of grass-land, which was forced upon the industry by the necessities of war, is already in process of reversal, and this return to grass is likely to proceed at an increasing rate unless clear evidence is forthcoming that arable farming for some years to come is likely to give such enhanced profits as compared with grass farming as will compensate adequately for the greater worries and outlay it entails. The gain to national security which the increased supply of home-grown breadstuffs obtainable from an enlarged arable acreage can confer is obvious, and that this is at the same time consistent with a profitable system of agriculture is amply demonstrated in the practice of Germany, Belgium, and the Scandinavian countries, where systems designed essentially for the production of corn, vegetables, and milk prevail.

It must not be too readily assumed, however, that these systems are directly applicable to British conditions, which differ in many respects, and, Mr. Mackenzie would warn us, in none more vitally than in the more refined taste in meat, *par excellence* beef, which marks us out as a race apart. The German and the Dutchman are apparently condemned by their systems of agriculture to a beef mainly derived from the carcasses of worn-out milch cows and draught oxen, but who could forecast the consequences of a change in our agriculture which would restrict the British workman—and the British cook—to such fare! Mr. Mackenzie has no doubt that it would lead to "a

general fall in our national standard of life," and have "a very pernicious effect on the efficiency of our race."

He would postulate, therefore, that no system of agriculture can be sound for this country unless it provide for an abundant supply of prime beef. We must hasten to explain, however, that he is no advocate of reversion to grass farming, which, indeed, he condemns roundly as "stealing from the land." Nor is he satisfied with other current systems of beef production. Taking the various systems at present in vogue, he has no difficulty in demonstrating that on the average British farm even the best of them represents but a very inefficient use of the possibilities of the soil.

A great deal of our grass-land can be made far more productive by suitable ameliorative treatment, but more fundamental than this is the need for improvement of the general quality of our breeding stock. It cannot be denied that, despite the pre-eminence of our best stock, the general level of quality of cattle found on the majority of our farms is deplorably low. This is in some measure due to the great development of our export of cattle, which has given to the foreigner the pick, whilst leaving for the home farmer only the moderate animals and the outcasts of our pedigree herds. Moreover, the class of animal which the foreigner demands is not that which is best suited to the present home requirements.

The export trade must continue to be an important feature of our pedigree stock raising, but it is high time that organised effort should be made through State action with the co-operation of landed proprietors and agricultural associations to encourage the development of types of cattle especially suited for our own purposes and to ensure their distribution over the farms of the country. With an improved type of cow, capable of producing a good yield of milk and early-maturing, well-fleshed progeny, it will be possible to combine intensive cultivation with the production at reasonable cost of the milk, beef, cheese, butter, and veal which the maintenance of a high standard of living requires.

There are many signs that the line of reorganisation which Mr. Mackenzie indicates is the one which British agriculture is most likely to follow, and it is sincerely to be hoped that his book will circulate widely amongst the leaders of agricultural opinion and the farming community generally. Last, but not least, his exposition of the need for greater provision for research in animal husbandry must be warmly commended. Without this the improvement of live-stock must remain to a large extent a blind groping after ends incapable of precise definition. C. C.

French Text-books of Chemistry.

(1) *Notions Fondamentales de Chimie Organique.* By Prof. Charles Moureu. Sixième édition. Pp. vii + 552. (Paris: Gauthier-Villars et Cie, 1919.) Price 16 francs.

(2) *Cours de Chimie à l'usage des Etudiants P.C.N. et S.P.C.N.* By Prof. R. de Forcrand. Deuxième édition. Tome 1. *Généralités—Chimie minérale.* Pp. viii + 437. Tome 2. *Chimie organique—Chimie analytique; Applications numériques.* Pp. 527. (Paris: Gauthier-Villars et Cie, 1919.) Price 14 francs and 18 francs respectively.

(1) AS a science develops and facts multiply and group themselves into laws and theories, the system of imparting knowledge is greatly simplified by using these generalisations as pegs upon which to hang the facts. Whilst this process is of the very essence of scientific growth, it is important not only that the theories should clothe the facts, but also that the tight or loose parts of the garment should be clearly marked in sartorial fashion for future modification. Nothing is more misleading than the attempt to adjust a theory by implication or by omission of details to limbs it does not fit. How flabby many a theory has looked on close inspection!

Herein lies a danger into which present writers on organic chemistry may fall. The mere enumeration of compounds has been replaced by the description of a few typical examples, and broad generalisations have been illustrated and condensed into a few paragraphs. This system of condensation, whilst it affords a useful survey of the whole region of organic chemistry, may in the process omit those apparently insignificant exceptions which, like the minute foreign substances in metals, modify the whole character of the material.

We have been led to express these views in the perusal of Prof. Moureu's treatise.

The fact that it has reached a sixth edition is sufficient evidence that, whatever its merits or defects, the book has established itself as a popular text-book, and that it should have so established itself is easy to understand.

The number of compounds described, though sufficiently numerous, is not more than is necessary to illustrate some general process. Each chapter and section is introduced by a few paragraphs on *généralités*, admirably and lucidly explained. The weak point of these *généralités* is their brevity. They merely touch the fringe of the subject, and as there are no references, the student is not encouraged to bridge the gaps. Tautomerism, which finds a place under ketonic acids, is dismissed in less than three pages.

Each new subject is introduced by a string of names of distinguished chemists who have been concerned in its study (sometimes as many as eight are given), but there is no indication of the nature of their contributions, and again no references are given. Incidentally, it may be pointed out that the names of French chemists are much in evidence. Under "Valency," Frankland's name is not even mentioned. These are minor points.

The arrangement, though somewhat novel to English chemists, is finding favour both in France and in America. There is no division into aliphatic and aromatic compounds, but the two are combined. Thus chap. ii. includes all the hydrocarbons, saturated and unsaturated, aromatic and hydro-aromatic, and the same system is followed throughout. The nitrogen compounds have a chapter to themselves, and there are others on organo-metallic compounds, heterocyclic compounds, and colouring matters.

(2) Prof. de Forcrand's class-book of chemistry, which has reached a second edition, is written for students who are entering on a course for the P.C.N. and S.P.C.N.—that is to say, a certificate sanctioned by the Ministry of Public Instruction for advanced study in physics, chemistry, and the natural sciences, the P.C.N. representing a standard intermediate between the *baccalauréat* and the *licencié* in science, and the S.P.C.N. being the equivalent of the latter.

The course is divided into two parts, inorganic and organic, which are treated in separate volumes. The inorganic section is divided into *généralités,* metalloids, and metals. The book is not intended for, nor is it to be recommended to, beginners. The general principles laid down in the first section, which include such notions as reversible and isomeric changes, the phase law, mass action, displacement of equilibria, etc., would be almost meaningless unless the student were already acquainted with the phenomena upon which these generalisations are built. Moreover, the subjects are presented in a didactic manner, in which general statements are laid down without any attempt at adducing evidence for them.

It seems to the writer that the old method, which was so common formerly among authors of science text-books, of introducing general principles and definitions before any experimental facts had been discussed, though perhaps philosophically sound, is not the best way of applying the experimental method—that is, the method of reasoning from facts to generalisations—and not only so, but it is almost bound to lead, as in the present case, to didactic treatment.

The same criticism applies to the volume on organic chemistry. The linking of carbon atoms by single and multiple bonds is assumed without evidence, and so also is the structure of the various organic groups.

Generally speaking, the book is somewhat old-fashioned in its arrangement, in spite of paragraphs on modern topics. It suffers, too, from a dearth of illustrations. Even if the student has studied his subject experimentally, and is acquainted with apparatus and methods, he is still ignorant of many practical operations of a technical character or special apparatus used in the preparation of rarer compounds which some good drawings would help him to grasp.

Having pointed out what seem to the writer the chief defects of treatment, it should be added that the information is well arranged, and covers the most important facts without unnecessarily multiplying the number of compounds. It is curious to find the subject of analytical chemistry, both inorganic and organic, relegated to the end of the volume on organic chemistry.

J. B. C.

Indian Beetles.

The Fauna of British India, including Ceylon and Burma. Coleoptera. Chrysomelidae (Hispinae and Cassidinae). By Prof. S. Maulik. Pp. xi+439. (London: Taylor and Francis, July, 1919.) Price 1 guinea.

THERE is evidence enough in this volume to show that many months of assiduous work must have gone to its preparation; but it leaves more than an impression that the author lacked experience to begin with, and had not quite mastered his subject. His descriptions are generally too long. An author of experience, using better judgment, would have confined his attention to essentials when describing species, and left out the rest, thus saving himself and his readers both time and trouble. It would have meant a lot in a volume like this, where 388 species altogether come under notice, and all but a few are described at length. Where the descriptions are long and the differential characters not clearly marked out, the keys to genera and species need to be well constructed and trustworthy.

Prof. Maulik's keys do not always answer to this description. His keys to species not infrequently contain diagnoses which, though fairly long, are not quite long enough to enable the text descriptions to be dispensed with altogether; and the key to his first group of genera is of so little service that the reader is left to decide which is the more to be trusted, the author or his artist, the key or the text. He has nowhere

explained why he has rejected certain characters made use of with great success by Chapuis in his grouping of the genera of Hispinæ; and it is to be noticed also that he has not stated why there is so very rarely any reference to sexual differences in his descriptions, either of genera or of species, which otherwise appear to show close observation.

About ninety of the species described are the author's own, and to many of these he has given names which, derived from the ancient language of his country, form a novel and interesting feature of the book. In a short introduction to each sub-family an account is given of the few larvæ and life-histories known, and a list of useful references to other works in which information about them may be found. Mimicry in the Hispinæ is touched upon, and Gahan's observations on the interesting stridulatory structures met with in the same sub-family are quoted almost in full, but without reference to the value they were expected to have for systematic purposes.

The volume is well illustrated, and the figures, all greatly enlarged, appear to be carefully drawn, with the exception of one on p. 86, which is not what it is said to be—the "mentum" of a genus which is unique amongst the Chrysomelidæ in having no labial palpi. Were it not for defects of the kind pointed out, and frequent signs of carelessness in the text, the volume, on the whole, would deserve much praise, due regard being given to the fact that it is the author's first essay in systematic work on more than a small scale.

C. J. G.

Mathematics: Pure and Applied.

(1) *The Fundamental Equations of Dynamics and its Main Co-ordinate Systems Vectorially Treated and Illustrated from Rigid Dynamics.* By Frederick Slate. (Semi-centennial Publications of the University of California.) Pp. ix+233. (Berkeley: University of California Press, 1918.)

(2) *Projective Vector Algebra: An Algebra of Vectors Independent of the Axioms of Congruence and of Parallels.* By Dr. L. Silberstein. Pp. vii+78. (London: G. Bell and Sons, Ltd., 1919.) Price 7s. 6d. net.

(3) *Elements of Graphic Dynamics: An Elementary Text-book for Students of Mechanics and Engineering.* By Ewart S. Andrews. Pp. viii+192. (London: Chapman and Hall, Ltd., 1919.) Price 10s. 6d. net.

(4) *Differential Calculus for Colleges and Secondary Schools.* By Dr. Charles Davison. (Cambridge Mathematical Series.) Pp. viii+309. (London: G. Bell and Sons, Ltd., 1919.) Price 6s.

(5) *The Analytical Geometry of the Straight Line and the Circle.* By John Milne. (Bell's Mathematical Series.) Pp. xii+243. (London: G. Bell and Sons, Ltd., 1919.) Price 5s.

(1) MANIFOLD adaptations of dynamical reasoning have given rise to specialised treatises of undoubted excellence. Prof. Slate sets himself the task of surveying the common foundation and the common stock of resources of these adaptations, as well as the trend of modern development in dynamics. Six quantities enter into the formulation of fundamental dynamical principles: force, power, and force-moment on one hand, momentum, kinetic energy and moment of momentum on the other. Each triad can be, and has been, used in the enunciations of dynamics. But the enunciations involve the use of reference-frames, leading to the question of the relativity of such frames and the transformation from one frame to another—both when the transformation is that of a mere translation, and when it partakes of the more general form of a shift and a rotation. The author considers these transformations and the chief kinds of co-ordinate systems. Euler's and Lagrange's equations, and their use in the study of the dynamics of a rigid body, conclude a presentation possessing considerable interest and originality. A number of notes are added containing references and further elucidations.

An objectionable feature of the book, and one that destroys much of its value, is the difficult English in which it is written. The most intelligible portions are those consisting of mathematical symbolism—the accompanying letterpress is often a puzzle. What is one, *e.g.*, to make of the following?—

> "In consequence it has not been displaced as a tenet of orthodox dynamical doctrine that standards by which to judge of the energy, momentum and force that ought to appear in its accounts will not stand on a par if adopted at random, however interchangeable they have proved in passing upon rest, velocity and acceleration by the mathematical criteria in the more indifferent domain of kinematics."

The impression one has in reading the book is that of a laborious progress over a succession of obstacles. Not every reader can be expected to persevere when so many of the obstacles are due to the guide whose function it should be to remove such difficulties as are inherent in the subject.

(2) In Dr. Silberstein's book on "Projective

Vector Algebra" we have a very lucid exposition of a subject somewhat removed from the ordinary interests of the mathematical teacher or researcher. Vectorial representation is a common feature of many branches of physical science, and the author's share in the encouragement of the use of vectorial methods amply justifies his further contributions to the discussion of the nature and properties of vectors, whether as means of calculation and research, or as illustrative of fundamental geometrical properties of space. The present book aims at the construction of an algebra of vectors, based solely on the axioms of connection and of order. Only addition and subtraction of unlocalised vectors are dealt with in the book itself; in a subsequent paper in the *Philosophical Magazine* the treatment is extended so as to include multiplication and division.

Opinions may differ as to the utility of the system thus constructed; there does not seem to be any obvious application of the ideas to the discovery of new results in pure mathematics or in investigations of a physical character. But the methods are elegant, and the exposition is admirable. The proofs afforded of theorems on the projective geometry of rectilinear figures and conics amply repay the few pleasant hours spent in reading the book and its continuation in the above-mentioned paper. One may perhaps question whether the book is really adapted for "beginners in geometry."

It would have added to the value of the investigation if the book had been divided into chapters and a reasonable number of examples inserted for exercise in the methods developed. The construction for scalar multiples of a vector admits of some simplification.

(3) This is a useful account of the application of graphical methods to dynamical problems, especially such as are of an engineering character. The process of graphical integration is applied to work, to space, to velocity and acceleration, and to action, the auxiliary parabola being used for the last. Polar diagrams are used with special application to simple harmonic motion and to combinations of simple harmonic motions, to cams, etc. Velocities changing in direction are then considered with applications to rotating bodies and the turbine. Linkages and static forces in mechanisms are followed by the elements of fly-wheel design and the theory of the balancing of rotating parts. There are many diagrams and exercises.

Though primarily intended for the engineer, the book contains much that should be incorporated into ordinary elementary courses on dynamics. Actual live problems with their practical solutions are far more valuable, pedagogically, than the numerous artificial exercises that are given in so many of the books written "for schools and colleges."

Mr. Andrews should take more pains with his notation; the needless use of x for ordinates must surely annoy the student. The statement

$$\text{mean effort} = \frac{\text{area below curve}}{\text{length of curve}}$$

(p. 14) needs obvious correction. The definition of work on p. 34 applies only to a force constant in magnitude and direction. On p. 47 simple harmonic motion is defined in the usual manner, but with the addition that the force acts in a direction opposite to the direction of motion of the body. This is not an oversight, for it is repeated on p. 64!

(4) This is not a book for beginners, although Dr. Davison follows the usual practice of indicating what might be omitted on a first reading. The whole book should be put aside on a first reading of the subject, and a more suitable presentation selected for the purpose.

But the student who has already mastered the elements of the calculus, and understands the meaning of a limit and the notion of differentiation and integration, is ready for Dr. Davison's book. It is brief, yet full. Part i. contains first principles—*i.e.* differentiation, successive differentiation, expansions, and indeterminate forms. Part ii. deals with the applications to maxima and minima, and to the theory of curves, including curvature, asymptotes, singular points, curve-tracing in Cartesian and in polar co-ordinates, envelopes, evolutes, and pedals. There are numerous examples, including sets of revision exercises. Two excellent features are the problem papers and the suggestions for a number of mathematical essays. The form of the book is pleasant, and the diagrams are well drawn and reproduced.

A few improvements are possible. Thus §§ 28 and 34 are ambiguously worded. There is a trap in the formulæ of § 61. In the chapter on polar co-ordinates nothing is said about the ambiguity inherent in polar equations, as mentioned in these columns in a recent review of another book. These are but a few blemishes in what is an excellent production on well-known traditional lines.

(5) There is much excellent matter in Mr. Milne's discussion of the analytical geometry of the straight line and circle. The treatment is lucid and such as will appeal to the beginner; the subject-matter is very well chosen, and presented in abundant detail with numerous illustrative exercises, both worked and unworked.

It is difficult, however, to recommend the book for general use in schools. Attention has been directed on several occasions to defective figures in elementary mathematical text-books. In Mr. Milne's book the fault exists in an accentuated degree. No attempt seems to have been made to co-ordinate the diagrams and the letterpress, whilst many of the diagrams printed on squared paper contain actual mistakes. These criticisms apply to diagrams on pp. 3, 34, 35, 36–37, 38, 53, 55, 58, 59, 63, 72, 74, 88, 92, 120, 123, 128, 129, 143 (a very bad case), 147, 148, 155, 157, 166, 179. It is surely not right to place such diagrams before young students.

If the book were re-issued with correctly drawn diagrams, it would constitute a valuable addition to school and college text-books.

S. BRODETSKY.

Our Bookshelf.

The British Journal Photographic Almanac and Photographer's Daily Companion, 1920. Edited by George E. Brown. Pp. 912. (London: Henry Greenwood and Co., Ltd.) Price 1s. 6d. net.

ALTHOUGH this volume has not quite reached its pre-war bulk, it has gone a long way towards it, and appears to be now lacking only a little in its former plethora of advertisements. Unfavourable conditions still hold, but the editor has been able to restore the tables, formulæ, and other technical details that photographers have for so many years been in the habit of consulting in their daily work. The "Epitome of Progress" is a good summary of the novelties of the past year, and there is, we think for the first time, a "History in Brief of Photographic and Photomechanical Processes." The nine pages devoted to this subject will be of special interest to the student, for they give the dates of a very large number of important facts connected with the development of photography, starting from the very beginning. We notice that sensitol red and sensitol green are ascribed to Prof. Pope in 1917. We always thought that these were pinacyanol and pinaverdol, respectively, of German origin some years previously, and that to Prof. Pope was due the credit of preparing them in this country, and also of introducing sensitol violet, which, however, does not appear to be mentioned. The section on "Beginners' Failures in Photography," by the editor, deserves much appreciation. C. J.

Toxines et Antitoxines. By M. Nicolle, E. Césari, and C. Jouan. Pp. viii + 123. (Paris: Masson et Cie, 1919.) Price 5 francs net.

M. NICOLLE holds such a high place among those who have made contributions of real importance to our knowledge of parasites that it seems a pity he should put out this disorderly summary of some of the researches of himself and his collaborators. It reads like a bundle of notes that a man might make to define the current position of his investigations, and to settle which piece of work he should take up next. With trivial exceptions M. Nicolle reviews no facts but those of his own discovery, and it is impossible to distinguish between conclusions and hypotheses. He points out, for example, the similarity of symptoms and anatomical lesions produced by various toxins of different origins, and the diversity and specificity of the antibodies which result from their introduction into the animal economy. He therefore concludes that toxins consist of two parts, one poisonous and not an antigen, the other inactive and an antigen. This is no more than a possibly fruitful hypothesis on which to base further experimentation. Those who know the subject well might run through the book with advantage; others had better leave it alone. A. E. B.

Some Wonders of Matter. By the Right Rev. Dr. J. E. Mercer. Pp. 195. (London: S.P.C.K.; New York: The Macmillan Co., 1919.) Price 5s. net.

BISHOP MERCER writes for children, and in a manner in accordance with the Child's Guide of our grandparents rather than with modern educational ideals. His primary concern is to excite the naïve wonder which he considers so valuable; so he makes no selection, but ranges apparently at random from Pharaoh's serpents to Brownian motion without giving any clue to the relative importance of the very varied matters at which he glances. So wide a range in so small a space would tax severely the highest powers of exposition, and Bishop Mercer has not the genius for happy analogy that is characteristic of all the most successful writers for the young. Again, though the work is free from serious error, we judge that its author has not a first-hand acquaintance with science. If he had, he would scarcely puzzle the brains of his small charges (and incidentally that of the reviewer) by raising questions no serious student of science would ask—those, for example, which give rise to the paradoxes of Berkeleyan idealism. On the other hand, some parents will welcome the definitely religious tone and be gratified that the Divine Intelligence is presented in a form sympathetic to the simplest.

An Arithmetic for Preparatory Schools. With Answers. By Trevor Dennis. Second edition, revised. (Bell's Mathematical Series.) Pp. xiv + 376. (London: G. Bell and Sons, Ltd., 1919.) Price 4s. 6d.

MR. DENNIS'S "Arithmetic" well deserves the second edition which it has reached. The sequence is based on the syllabus of mathematical teaching for ages nine to sixteen, for non-specialists, issued by the Curriculum Committee of the Headmasters' Conference. Suitably chosen exercises and clear type make the book well adapted for the students for whom it is intended.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Museums and the State.

I HAVE read with deep interest the leading article entitled "The State and the National Museums" which appeared in NATURE of March 11. As a zoologist my interest is chiefly centred in the Natural History Museum at South Kensington, and I most heartily agree with the statement that "the development of the Natural History Museum has been grievously hampered by the persistent attempt made to fit it to a system devised . . . especially for the great library [at Bloomsbury], which has, in fact, always tended to overshadow the rest of the museum."

Historically, as you point out, the museum at South Kensington is the offspring of the mother institution at Bloomsbury, but the daughter is now fully grown up, and should be completely free from parental control. It seems quite anomalous that a man chosen for his knowledge of antiquities and literature should be the supreme head over the greatest collections of animals and plants which exist anywhere in the world.

Few Englishmen have any adequate idea of the value of the asset represented by these collections. Most of them, like Lord Sudeley, whom you quote, regard the museum merely as an instrument of popular education. But this is only one of its lesser functions. Its main value lies in the fact that it is the repository of type-specimens of the majority of the determined species of animals and plants. In these days of the energetic development of newer lines of research in zoology, it must never be forgotten that systematic zoology is the basal science, the pre-requisite for successful advance in any other branch of the subject.

Just as it is necessary that standard measures of length, weight, etc., should be stored in some central repository, so it is necessary that there should be a central institution in which every biologist should be able to determine accurately the species with which he is working. The agriculturists of Mauritius are bothered by an insect pest which they regard as identical with one of the common insects of the island. Measures are taken for its extermination, and these prove unsuccessful. It is then discovered, on reference of the matter to South Kensington, that the pest is a foreign one accidentally imported from the West Indies! Examples of this kind could be multiplied indefinitely, but one more may suffice. The fishery authorities of South Africa desired to introduce the herring into their coastal waters, but the experts at South Kensington were able to point out that, although different species of herring exist in various parts of the world, in both northern and southern hemispheres and east and west, yet all these species are confined within the limits prescribed by two isotherms of annual temperatures, and that South Africa lies outside these limits; so that if herring were liberated near its coast, they would, if they survived, at once swim southward into cooler waters.

The supreme government of the two museums at Bloomsbury and South Kensington is vested in three principal trustees, viz. the Archbishop of Canterbury, the Chancellor of the Exchequer, and the Speaker of the House of Commons, not one of whom has any necessary connection with or knowledge of science.

The scantiness of this knowledge may, indeed, be gauged by the scornful remarks made by the Speaker during the war in reference to the alleged purely academic interest of studies on Microlepidoptera at the very time that the War Office was imploring the aid of specialists in this department in fighting a pest which was destroying its stores of biscuits.

The article in NATURE advocates placing the museum under the control of a Government Department—"*Timeo Danaos et dona ferentes.*" It seems to me that the ideal of the present Government, viz. a small committee of broad-minded men, is the correct one; only the *personnel* requires to be changed.

It has been cynically observed that the constitution of the present committee was chosen at a time when the Archbishop, the Chancellor of the Exchequer, and the Speaker were the three men in England least likely to be bribed. If for them were substituted the presidents of the Royal Society, of the Zoological Society, and of the Geological Society, the control of the museum would be in the hands of a committee of scientific eminence, and one peculiarly susceptible to the pressure of scientific opinion.

In view of the unique importance of the collections, it is surely essential to have a distinguished man of science presiding over each division of the collection, and for the services of such a man the museum ought to be in a position to pay generously. In the past the museum has been far better served than it deserved to be; it has, in fact, exploited the scientific enthusiasm of young men. In the long run, however, low pay will evoke inferior service. As the present holders of positions in the museum die or resign, clever men will be reluctant to step into their places if to do so means to embrace a life of poverty. A governing body such as I suggest would be in a far better position to estimate the real value of the services of these experts than one which is too much inclined to regard them as a set of obscure academic recluses.

E. W. MACBRIDE.

Royal College of Science, Zoological Department, South Kensington, London, S.W., March 12.

THE leading article in NATURE of March 11 on "The State and the National Museums" directs attention to a reform the need for which has been increasingly felt by those especially interested in our great national museums. Your summary of their haphazard history explains why their relation to the Government is out of date; why between them there is an overlap which, despite the advantage of competition, causes waste and inconvenience and is a hindrance to efficiency; and why our Museum of Natural Science is administered by a board of trustees planned—so far as it was planned and has not been a fortuitous aggregate of distinguished men—in reference to the library and departments at Bloomsbury. The titles of the museums are a product of this erratic growth and misleading to the public; the Natural History Museum is actually the British Museum of Natural Science, since, according to recent usage (*cf. e.g.* Webster's Dictionary), natural history is restricted to zoology, or perhaps to biology, while the adjacent museum is the British Museum of Physical Science.

Dissatisfaction with our museum administrative system has been clearly growing for years, but there has been no particular opportunity to secure reform or to organise a sufficient body of opinion to convince the Government of its need. Now, however, the establishment of the Department of Scientific and Industrial Research has provided an organisation to which the management of the scientific museums might be appropriately entrusted.

The suggestion, however, to extend that Department so as to include all learning and research requires cautious consideration, since it would throw on that

Department duties so dissimilar as the management of scientific and artistic collections, and would jeopardise its scientific position. One great advantage of that Department is that it provides one strong and influential organisation devoted to the development and utilisation of science; but if it had to control all literary and classical research its aims would be diffuse, and pure science, between the claims of the "humanistic" and industrial sections, might fare poorly.

To unite all our museums, artistic and antiquarian, classical and commercial, scientific and military, under one control would maintain the practice that a museum is a "raree" show, and be inconsistent with the modern principle that a museum is primarily laboratory of which the general policy should be determined by the authorities in its own department of knowledge. To place a technical or research museum under the Board of Education is as anomalous as to place some other museums under a research department. There are museums in London—for example, that at Bethnal Green—which would be appropriately managed by the Board of Education or by the Education Committee of the London Country Council as the demonstration department of the East London schools.

The foundation and original endowment of the British Museum by a State lottery introduced into British museum policy a virus of chance, which has since been a potent factor in the development of the museums; but a commission of inquiry might now secure sufficient support to establish them on a firmer foundation and utilise the unique opportunities of London as the home of a well co-ordinated group of world-representative museums. The present medley, in spite of its unrivalled material, is being outclassed by the museums of America. J. W. GREGORY.

4 Park Quadrant, Glasgow.

THOSE who have long viewed with increasing irritation the waste of time, labour, and money involved in the present unco-ordinated condition of our national museums will welcome the leading article in NATURE of March 11, in which you have with such justice expounded the situation and indicated a possible solution of our difficulties. It is a little dangerous for a Civil Servant to express a candid opinion on the workings of Government Departments, but perhaps I may be allowed to go outside that taboo area and to point out that the duplication of work and the competition for specimens to which you have alluded affect all the museums (including art galleries) of the country. Some of us, therefore, have come to the conclusion that these also should be co-ordinated with the national institutions and knit into a single scheme. There need be no interference with the existing direction of each museum, but there could be much organised help.

We of the geological department of the British Museum do, in a small, disjointed way, try to help our colleagues of other museums, and we receive help from them. But this is just enough to let us imagine what could be done if such mutual aid were placed on a recognised footing; if, for instance, the small band of museum palæontologists of Great Britain (and Ireland?) was so organised as to cover the field, and so employed that each specialist could help and advise on his own subject in all museums as part of his official duties. At the first meeting of the Museums Association in 1890 a committee was appointed to consider some such co-operation, but little practical result has ensued, not for lack of goodwill, but because existing conditions stand in the way. What applies to palæontology applies to all other branches of knowledge. But this is only one of the improvements that might spring from a reform such as we have in view.

Many other good results there could be, among them, perhaps, a better training for curators. But that the results shall be good it is necessary for the directing board to be composed of men with museum sympathies and experience. Therefore, whether the Ministry be that of Education or some new Ministry of Learning and Research, it should exert its financial or other control over museums through a special museum board. In this way those branches of museum work which do not meet the public eye would run less risk of being overlooked. Any large natural history or other science museum is part of the armament employed by man in his unceasing warfare against the forces of Nature. Intellectually and economically that is its main purpose. As the Earl of Crawford, in replying for the Government on the debate raised by Lord Sudeley, rightly said: "It is not the popular guide-books, but the technical and specialised publications issued by museums which really count. They are of vital importance." Visits to a museum, like visits to a battleship, may be of high educational value, especially under the guidance of a qualified demonstrator, but—well, the inference is obvious. Only one point needs emphasis. Museums, no less than battleships, should be under the administration of those familiar with the principles and methods of the respective warfares.

F. A. BATHER.

Wimbledon, March 13.

THE relation of the State to the national museums, and of the latter to each other, discussed in NATURE for March 11, is a matter calling for very careful consideration at the present time. A Ministry of Learning and Research, such as is there suggested, would render very useful service if it could (1) see that the governing body of each institution was composed of persons duly qualified for their work; (2) define the scope of each institution, so as to diminish the risk of competition for desirable specimens, and to provide each with a definite piece of work for the benefit of the community; (3) provide each institution with a due proportion of financial assistance; and (4) arrange such a scale of salaries as would ensure the appointment and retention of the brains best adapted for the purpose in view. At this point central control should cease, and each governing body be left to do its own work, with the assistance of its staff.

The proposal to place museums and libraries under the Board of Education, to which the article alludes, has no reference, I believe, to national museums, but I should like to place on record my strong disapproval of such a step. A museum has many duties to perform, and education in the sense in which the Board deals with it is only one, and not the most important, of them. On the basis of a very extensive acquaintance with provincial museum curators, I have no hesitation in saying that they are fully alive to the educational possibilities of their work. Many of them have rendered valuable service to the education authorities of their localities, and many more would have done so had they been permitted; but this does not prevent them from seeing that their museums have other functions to perform which do not fall within the purview of education committees as at present constituted. In the first place, they are storehouses of material for enlarging the bounds of human knowledge; secondly, they provide objects of interest and beauty for the intellectual and æsthetic contemplation of the citizen; and, thirdly, they furnish material for the university student, post-graduate and undergraduate, as well as for children of school age.

May I say in conclusion that, in my opinion, the

chief thing that is wrong with museums, national and provincial, is (as Bernard Shaw says of the poor) their poverty? WM. EVANS HOYLE.

National Museum of Wales, Cardiff,
March 15.

IN the timely and suggestive leading article on museums in NATURE of March 11 there are references to the Museum of Practical Geology that need explanation, not because they are incorrect, but because they are symptomatic of that forgetfulness of the fundamental purposes of this museum which has long been obvious in some quarters.

It is true that "the Museum of Practical Geology was a necessary concomitant of the Geological Survey," but this was not, and never has been, its sole *raison d'être*. It was founded as the Museum of Economic Geology—that is, of economic geology in its broadest aspects. It had, therefore, from its inception two functions to perform: (1) To serve as the storehouse and exhibition for all the concrete documentary material collected during the making of the geological maps—material of the greatest value as a demonstration of the facts of British geology and usefully employed for educational, industrial, and purely scientific purposes; and (2) to act as the national repository of material illustrative of all those mineral resources that form the basis of mining, metallurgical, and other industries.

The first of these functions is purely British in scope, the second is world-wide.

As regards overlapping with the Natural History Museum, there is none; and alternatively, as the lawyers say, if there is any it should cease, since the functions of the two institutions are clearly differentiated. The scheme of the geological and mineralogical departments of the Natural History Museum is academic, and that of the Museum of Practical Geology economic. On the other hand, the Imperial Institute in respect of its mineral exhibits does overlap the functions of the older institution. This is a question requiring attention in any scheme of reconstruction. WILLIAM G. WAGNER.

March 15.

Some Methods of Approximate Integration and of Computing Areas.

ENGINEERS and shipbuilders are continually requiring to find the area of a surface bounded by curved lines. If both the upper and lower boundaries are curved, it is a simple matter to divide the surface into two by a straight line, find the area of each part separately, and add them together.

Simpson's rule is almost universally used for this purpose, but a little consideration will show that a more accurate evaluation of the area can be obtained in most cases by using other rules.

We will consider an area contained by a base line, two vertical ordinates at the ends, and a number of intermediate ordinates placed at equal distances along the base line. If the base line be divided into m equal intervals, each of a length h, there will, of course, be $m+1$, or n, ordinates. When the height of these ordinates is known, and the value of h the interval also, an approximation to the value of the area can be obtained which increases in accuracy with the number of ordinates taken and measured, when the curve is of an anomalous shape.

(1) If the upper boundary be a straight line, an exact result will be obtained by merely the two end ordinates y_1 and y_2 and the length of the base line h; $A=\frac{1}{2}h(y_1+y_2)$.

(2) If, the upper boundary be a parabola, an exact result will be obtained by bisecting the base line, and then

$$A=\frac{h}{3}\left(y_1+y_3+4y_2\right),$$

where h is half the base line.

This is Simpson's well-known rule: If any odd number of ordinates be taken, say 7, it is considered as a succession of three areas bounded above by three parabolas, *i.e.* the area from y_1 to y_3 is added to the area from y_3 to y_5, and this, again, is added to the area from y_5 to y_7. The formula used is then

$$A=\frac{h}{3}\left[\overline{y_1+y_7}+2\,\overline{y_3+y_5}+4\,\overline{y_2+y_4+y_6}\right].$$

If m denote the number of additional areas computed by this method, the general formula will take the form

$$A=\frac{h}{3}\left[\overline{y_1+y_{3+2m}}+2\,y_{1+2m}+4\,\overline{y_2+y_{2+2m}}\right].$$

It should be especially noted that this formula must be used only when the number n of ordinates is odd and the number of intervals even. In the second and third terms the values 1, 2, 3, etc., are assigned successively to the symbol m, ending with that value of m which denotes the number of additional areas that are to be computed. The formula is based on the assumption that $y=a+bx+cx^2$, and gives the best possible approximation to the true area if only three ordinates are given.

(3) If, however, four ordinates be given, we may assume that $y=a+bx+cx^2+dx^3$, and the resulting formula based on this assumption,

$$A=\frac{3h}{8}\left[\overline{y_1+y_4}+3\,\overline{y_2+y_3}\right],$$

will give the best possible approximation if only four ordinates are given. This formula should be used only when the number of ordinates is $4+3m$, and it then becomes

$$A=\frac{3h}{8}\left[\overline{y_1+y_{4+3m}}+2\,y_{1+3m}+3\,\overline{y_2+y_3+y_{2+3m}+y_{3+3m}}\right].$$

(4) If five ordinates be given, we shall obtain a more accurate result by assuming that y is a quartic function of x, and for 5, 9, 13, or $5+4m$ ordinates the following formula may be used:

$$A=\frac{2h}{45}\left[7\,\overline{y_1+y_{5+4m}}+14\,y_{1+4m}+\right.$$
$$\left.12\,\overline{y_3+y_{3+4m}}+32\,\overline{y_2+y_4+y_{2+4m}+y_{4+4m}}\right].$$

(5) Similarly, if $6+5m$ ordinates be given, y may be regarded as a quintic function of x, and the formula becomes

$$A=\frac{5h}{288}\left[19\,\overline{y_1+y_{6+5m}}+38\,y_{1+5m}+\right.$$
$$\left.75\,\overline{y_2+y_5+y_{2+5m}+y_{5+5m}}+50\,\overline{y_3+y_4+y_{3+5m}+y_{4+5m}}\right].$$

(6) Again, if $7+6m$ ordinates be given, y may be assumed to be a sextic function of x, and we then have the formula

$$A=\frac{h}{140}\left[41\,\overline{y_1+y_{7+6m}}+82\,y_{1+6m}+\right.$$
$$216\,\overline{y_2+y_6+y_{2+6m}+y_{6+6m}}+$$
$$\left.27\,\overline{y_3+y_5+y_{3+6m}+y_{5+6m}}+272\,\overline{y_4+y_{4+6m}}\right].$$

In all these formulæ the first term consists of the sum of the first and the last ordinate. In (2), (3), (4), (5), and (6) the values 1, 2, 3, etc., are assigned successively to the symbol m in the following terms according to the number of ordinates. Thus if in (6) nineteen ordinates are given, $19=7+6m$, so $m=2$.

When $m=0$, the ordinates with m as a part of their subscript are omitted in all but the first term.

Example.—Suppose the base line be divided into six equal intervals ($h=\frac{1}{6}$), and the value of the ordinates be

$$y_1=0 \qquad y_2=0{\cdot}5527708$$
$$y_3=0{\cdot}7453560 \qquad y_4=0{\cdot}8660254$$
$$y_5=0{\cdot}9428090 \qquad y_6=0{\cdot}9860133$$
$$y_7=1$$

As seven ordinates are given, we may use any one of the rules (6), (3) which is adapted to $4+3m$ ordinates, and (2) which can be used when $3+2m$ ordinates are employed. We should expect to get a more accurate result when the higher-order formula is employed, and this we shall find to be correct. The values given refer to the quadrant of a circle, so that the true value is $\pi/4$, or $0{\cdot}78539816$ . . .

By method (6), putting $m=0$, the result is 0·7791866, *i.e.* 0·7972 per cent. too small.

By method (3) the result is 0·7758061, or 1·342 per cent. too small.

By method (2) the result is 0·777531, or 1·063 per cent. too small.

This result is curious, and shows that a small arc of a circle approaches more nearly to a small arc of a parabola than to a small arc of any cubic curve, but it will be noted that method (6) gives a much more accurate result.

We may, however, use a combination of the above rules; for instance, we may take five ordinates by rule (4) and the remaining two intervals by rule (2). As the first three ordinates increase more rapidly than the last three, we should naturally leave the last three to be dealt with by rule (2). In this way a result of 0·77784954, or a defect of 0·0069027, or an error of only 0·88667 per cent. is obtained. Had we reversed the order and used Simpson's rule for the first two intervals, the defect would have been 0·0078447, or an error of 1·0102 per cent.

In conclusion, it may be stated that if the nature of the curve is unknown a more accurate result will always be obtained by using the highest-order formula that can be used with the given number of ordinates. If two different formulæ are used, it has just been shown that the most accurate result is obtained when the higher-order formula is used for that part of the curve in which the variation of the ordinates is the greater. If the curve be a parabola, an absolutely accurate result is obtained by using only three ordinates by means of method (2).

It may be thought that plotting the curve and estimating its area mechanically by means of a planimeter will be always the best and speediest method to adopt, but this is by no means the case. It often takes far less time to calculate, say, thirteen ordinates and to use method (6) than to trace the curve.

An Electronic Theory of Isomerism.

THE interesting suggestions made by Mr. W. E. Garner in NATURE for February 19 with regard to a possible explanation of the isomerism of certain organic compounds may be examined from a different, but perhaps simpler, point of view by employing the "ring electron" or "magneton" of Mr. A. L. Parson. The electron is looked upon as a circular anchor ring of negative electricity rotating about its axis at a high speed, and therefore behaving like a small magnet. In connection with atomic and molecular numbers I have directed attention elsewhere to the "rule of eight," according to which a difference of 8 or a multiple of 8 is frequently found between the numbers of the unit electric charges associated with analogous atoms or molecules. In the theory of the "cubical atom" put forward by Prof. Gilbert N. Lewis and developed by Dr. Irving Langmuir, one of the most stable configurations for the atomic shell is that in which eight electrons are held at the corners of a cube. The single bond commonly used in graphical formulæ involves two electrons held in common by two atoms (Fig. 1); the double bond implies that four electrons are held conjointly by two atoms (Fig. 2) Or if the *pair* of electrons be regarded as the most stable grouping of all, it may be, as Lewis and Langmuir suggest, that the pairs of electrons held in common by two atoms are drawn closer

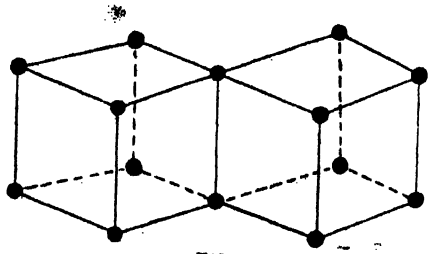

FIG. 1.

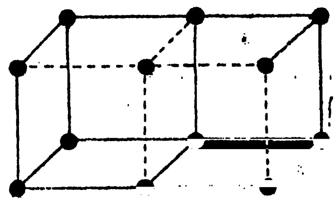

FIG. 2.

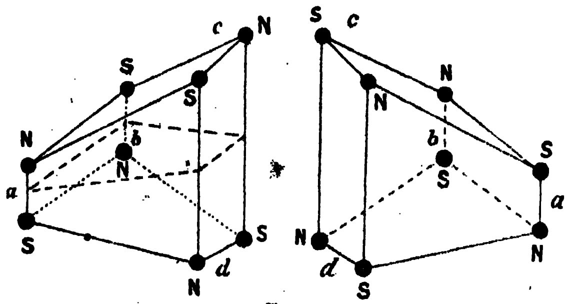

FIG. 3.

together by the magnetic attraction between them. Dextro- and lævo-rotatory forms of a compound might then be represented as mirror images as in Fig. 3. The letters N and S in this diagram may be taken to represent the polarity of the external face of the ring electron.

Mr. Garner suggests the possibility of the existence of a large number of optical isomerides amongst organic compounds, but the view here put forward does not lead to that conclusion; on the contrary, it seems to give exactly the same number of isomerides as the ordinary structural formulæ. It is true that it is possible to reverse *in the diagram* the magnetic polarity of one or more pairs of electrons, but even if the arrangements so obtained were stable, it is doubtful whether they would represent different isomerides. It would not be possible to explain the phenomenon of free mobility about a single bond

which is assumed in stereo-chemistry if such a reversal of the magnetic axis were accompanied by a change in the nature of the compound. Such modifications, however, might conceivably account for muta-rotation. It was thought that in the case of a double bond, such as exists in cinnamic acid, it might be possible to have a larger number of isomerides than would be given by the ordinary theory, but a close examination of the structural formulæ based on the cubical atom has shown that (subject to the limitation already referred to) this is not so.

The view here suggested appears to afford an adequate basis for a theory of optical activity. Such activity arises from a difference effect, and can be manifested only when there is lack of compensation amongst the electrons associated with the various parts of the molecule. If the chemical bond is to be attributed to a *pair* of electrons, it is easy to understand how such compensation can be brought about in the great majority of chemical compounds. In the case of a single asymmetric carbon atom, the symmetrical arrangement of each of the four electron pairs is disturbed by the presence of the adjacent groups, resulting in only partial compensation. Thus in the compound $Cabcd$, the pair of electrons associated with group a is under the influence of the unlike groups c and d, and, therefore, cannot be symmetrical. But if c and d are made alike, the whole molecule will have a plane of symmetry indicated by the broken line in the left half of Fig. 3. Thus the molecule will be inactive through "internal compensation" with respect to the electrons which form the outer shell of the carbon atom. I may add that the ring electron, constrained to move backwards and forwards along its linear axis, is admirably adapted to replace the ordinary electron moving backwards and forwards along a spiral path postulated in Drude's theory of rotatory liquids.

It may be permissible in this connection to emphasise the remarkable success that has attended Langmuir's development of the "octet" theory, by means of which it is possible to predicate the physical and chemical qualities of a substance, and even its crystalline structure. Langmuir states that the theory seems to explain all the cases of stereo-isomerism with which he is familiar. "For example, in the amine oxides, $NR_1R_2R_3O$, nitrogen is quadricovalent, so that these substances exist as optical isomers, just as in the case of a carbon atom attached to four different groups." Such a compound is, in fact, represented by the diagram already given. H. S. ALLEN.

The University, Edinburgh, March 2.

The Principle of Equivalence and the Notion of Force.

I SHALL be grateful to be permitted to make an inquiry in connection with the principle of equivalence through the medium of the columns of NATURE.

In the recent forms of the theory of relativity it has been asserted that in the neighbourhood of matter we may alternatively conceive the existence either of a field of gravitational force or of a distortion in the space-time continuum, the two conceptions being equivalent. The point then arises, however, as to whether, in arranging the body of ideas and propositions constituting physical science in logical sequence, the idea of force (at any rate, "force" in the sense of "action at a distance") or that of distorted space-time should be regarded as logically prior. The possibility of adopting the idea of distorted space-time as prior, and hence of finally dispensing with the notion of force from the physical scheme, evidently depends on a further generalisation of the principle of equivalence. For a difficulty seems to arise in connection with other forms of action at a distance, such as the forces in a magnetic or an electrostatic field. Apparently we cannot regard these as equivalent to a space-time distortion, for they lack the universality of gravitation, seeing that only bodies of specific types of material are deflected by them.

I should therefore like to ask two questions:

(1) Is it possible to extend the principle of equivalence in any way so as to include *all* forms of action at a distance?

(2) If not, is there anything gained, even from a purely logical point of view, by discarding the notion of gravitational force while we are still unable to discard *by the same method* the notion of certain other forces which in many respects exhibit a close analogy to gravitation? C. A. RICHARDSON.

Expenses of Scientific Work.

A JOINT committee of the British Association of Chemists, the Institute of Chemistry, and the National Union of Scientific Workers is putting forward the claim that the following expenses should be allowed as a charge against income in arriving at the assessment of those who earn their living either by purely scientific pursuits or by the application of science to industry:—

(1) Subscriptions to scientific and technical societies and libraries, and to scientific and technical periodicals.

(2) Purchase and renewal of scientific and technical books, instruments, apparatus, chemicals, and other materials.

(3) Rent and expenses of study or laboratory.

(4) Travelling and other expenses incurred in attending scientific meetings.

(5) Provision of special clothing for work and renewal of clothes damaged in the course of employment.

(6) Other expenses incurred in the course of research.

A form of memorial to be presented to the Lords of the Treasury is being sent to all bodies representative of scientific workers for their consideration and support.

Some claims for abatements under the above headings have already been made by individuals with varying success. I should be grateful for any information available in support of the petition.

A. G. CHURCH,
Secretary.

National Union of Scientific Workers,
19 Tothill Street, Westminster,
London, S.W.1, March 15.

Scientific Reunions at the Natural History Museum.

I WRITE to correct a small error that has crept into the note on the meeting of the International Council for the Exploration of the Sea which appeared in NATURE for March 11. When the members of that council visited the Natural History Museum on March 2 they were entertained, not by the Trustees, but by the Staff Association, the occasion being a scientific reunion, as was, indeed, stated in a later note in the same issue. I may add that these reunions are held with the approval and permission of the Trustees. G. F. HERBERT SMITH,
Hon. Secretary.

Natural History Museum Staff Association.

The World's Production of Silver.

THE recent action of the Chancellor of the Exchequer in introducing a Bill into the House of Commons for the purpose of debasing the silver currency from 925 to 500 parts per 1000 has directed public attention to the acute shortage of silver which exists. This action is unavoidable if a silver currency is to be maintained, since the price of the metal has risen so much that coins are no longer tokens. They are, in fact, worth to-day considerably more than their face value, and there is, accordingly, a temptation to melt them down and sell them for the considerable profit that the transaction would bring in. Such a procedure is, of course, illegal. In the years preceding the war the market price of silver, while subject to fluctuations, was never far from 2s. per "standard ounce." This expression is rather unfortunate, since it is not the ounce that is standard, but the quality of the metal. Its real meaning is a troy ounce of silver alloy containing 92·5 per cent. of the metal. With standard silver at about 5s. 6d. per ounce, the coins reach parity. During recent weeks the market price has fluctuated between 7s. and 7s. 5d. per ounce, though it is true that a remarkable fall of 6⅛ in the price took place on March 5, and a further fall of 5⅛ on March 11, owing largely to the improvement in the exchange with the United States of America. As stated, however, the Chancellor's action is necessary, since the minting of silver coins is possible only at a heavy loss. Nevertheless, this Bill was opposed in the House, although the opposition was not carried to a division.

It so happens that in January this year the report and appendices of the Committee appointed by the Secretary of State for India to inquire into Indian exchange and currency were published and presented to Parliament. In vol. iii. will be found appendix xxx., which contains a report on the world's production of silver.[1] This is the work of Prof. C. Gilbert Cullis and Prof. H. C. H. Carpenter, who at the request of the Secretary of State for India undertook an inquiry more than a year ago into the output of silver during recent years in the various silver-producing countries; the prospects, so far as they could be estimated, of future output; and the causes by which it is likely to be influenced. Their report covers some sixty foolscap pages. The subject-matter is presented in five main sections dealing severally with the raw materials from which silver is obtained, the location and quantitative importance of centres where silver-bearing ores are mined, the processes involved in the extraction of the metal, the distribution and relative importance of the centres where refining is carried out, and the conclusions affecting the supplies and price of the metal.

It appears from this report that in 1860 the world's production of "fine"—*i.e.* pure—silver was 30 million ounces. With some fluctuations this increased steadily until 1912, when the output was 233 million ounces, or nearly eight times that of more than half a century earlier. From that date, although a continuance of the upward trend was to be expected, a decline in production set in and continued down to the end of 1917, which was the last year for which complete figures are available. It is clear from the report that this reduction in output is assignable not to any sudden failure of the world's resources, but to an interruption in the winning of them.

The main source of the supply of silver ore is the American Continent, which in 1912 produced 82·5 per cent. of the total output. Approximately three-quarters came from North America and Mexico, the former furnishing 42 per cent. and the latter 32 per cent. Mexico was the largest single producer. A decrease in Canadian production had set in shortly before this, due to the progressive exhaustion of the Cobalt mines, but this was more than compensated by an increase in the production of the United States. The key to the shortage of the world's supplies is to be found in Mexico, where, owing to a series of political revolutions, the production fell from an average of close upon 74 million fine ounces for the years 1910–13 to an average of little more than 30½ million fine ounces for the years 1914–17, a reduction of some 43½ million out of a total reduction of 50½ million ounces in the world's output.

This serious diminution in the supply came at a time when, owing to the withdrawal of gold from circulation on account of the war, there was an unusually keen demand for silver, particularly for coinage purposes. The report of the Currency Committee points out that the coinage of the British Empire absorbed nearly 108 million ounces of fine silver in the years 1915–18, as against 30½ million ounces in the years 1910–13, and there is evidence that there have been similar increases in the coinage of other countries. Moreover, whereas China from 1914–17 was a seller of silver, and her net exports amounted to more than 77 million ounces, she has since become a persistent buyer, and the recent remarkable rise in the price of the metal is due to her purchases. India has for many years been a heavy buyer of the metal, and in times of normal trade was the largest importer of this commodity. War conditions have accentuated this, and in the three fiscal years April, 1916, to March, 1919, purchases for the purpose of liquidating trade balances amounted to more than 500 million ounces, which was probably very nearly the entire world's production for the period. These have been the chief (but not the only) factors in raising the price of silver to its extraordinary level.

It is clearly seen from the report that silver is mainly obtained as a by-product from mines which are worked for some other metal or metals.

[1] Vol. iii., Appendices to the Report of the Committee appointed by the Secretary of State for India to inquire into Indian Exchange and Currency. No. xxx., "Report on the World's Production of Silver." By Prof. H. C. H. Carpenter and Prof. C. Gilbert Cullis. Pp. 182–241.

Relatively few properties are worked solely or even mainly for silver, and only a small proportion of the world's supply has of late years been derived from them. It is therefore essentially a by-product. The more important economic metals with which it is most commonly associated are gold, copper, lead, and zinc. These five metals tend to be gregarious, and many deposits contain all of them. It is also found with tin, as in Bolivia, and with nickel and cobalt, as in Ontario, but such cases are uncommon. Although in different regions or in different parts of the same region the above five metals are found in a great variety of combinations, certain of these are particularly common. Thus gold and silver almost invariably occur together either with or without base metals. Again, lead and zinc nearly always accompany each other, and ores carrying these two metals, notably those in which lead predominates, are often richly argentiferous, the lead and silver forming an especially characteristic association. Copper in like manner is usually accompanied by small quantities of gold or of both gold and silver. The presence or absence of base metals in silver-yielding ores is of particular importance, since it determines the existing diversity in their metallurgical treatment and occasions their classification into two groups, known respectively as "milling ores" and "smelting ores," the former signifying those in which the values are entirely or mainly in precious metal. From the figures quoted in the report, it appears that, broadly speaking, about two-thirds of the world's supply of silver in 1912 was obtained from base metal, and one-third from precious metal, ores. Further, only one-fifth was obtained from mines worked exclusively for silver, while four-fifths was derived as a by-product from mines which were worked primarily for one or more of the metals—gold, copper, lead, and zinc—and would not have been in operation if their silver had been the only metal present. Formerly, the precious metal ores were the more important source of supply, but in the last few decades more and more of the metal has been won from base metal ores. It will be seen, therefore, that the authors, in endeavouring to estimate the future production of silver, have been forced to take into consideration the mining and metallurgy of four other important metals as well.

It is stated in the report that in 1912 the New World—*i.e.* the American Continent—furnished 82·5 per cent., and the Old World only 17·5 per cent., of the mine production of silver. The output in the British Empire was 21·7 per cent. Mexico led with 32·0 per cent., followed closely by the United States with 28·3 per cent. Towards the production of refined silver the New World contributed 73·0 per cent., and the Old World 27·0 per cent., the contribution of the British Empire being 18·2 per cent. The interesting fact emerges that the United States of America refined just about one-half the world's silver (49·6 per cent.), whereas Mexico refined only 14·2 per cent. More than half the Mexican mine production was refined in the U.S.A., and very nearly the same proportion of the Canadian output. It will be seen, therefore, that the position now held by the U.S.A., as the chief source of supplies of refined silver, is one of considerable importance. The same is true to an even greater extent for the metals copper and zinc.

The authors' view of the future is that if normal industrial conditions are restored in regions of curtailed production, a silver output at least as great as any yet attained may reasonably be anticipated. If, however, conditions affecting industry in general, and mining and metallurgical industries in particular, do not become favourable in these regions, a long period must elapse before the world's output can return to the previous high-water level, and a still longer one before the advance beyond that level interrupted since 1912 can be resumed. So long as the political conditions remain unsettled in Mexico, supplies from that country will continue to be small. This is particularly serious, because of the large dimensions of the normal Mexican output.

With the demand for silver more urgent than any previously experienced, the restoring of the mines and mills of Mexico to unhampered production has become a matter of pressing international importance. It must be borne in mind, however, that any extension in the mining of precious metal ores will take time, and that the mining of base metal ores is for the moment below normal, and will continue so as long as the surplus supplies of copper, lead, and zinc produced during the war remain unabsorbed. Silver production will probably, therefore, remain for a time at a low level. When, however, increased precious metal mining reaches the production stage, and the temporary check to base metal mining has been removed, the authors anticipate a steady increase in the output of the metal.

It is well to remember that, although silver has long occupied an important position as "second string" among metals suitable for currency, there are important industrial demands for it for other purposes. It is only necessary to mention two of these. First, in addition to the mechanical properties which make it valuable as a currency metal, there are others which have long been known and utilised in the silversmith's art. Standard silver lends itself readily to rolling, stamping, spinning, and mechanical operations employed in the manipulation of the metal in the arts, and upon them important industries giving employment to many workers are based. Secondly, the well-known sensitiveness of silver salts to light, made use of in photography, is being increasingly utilised in the "moving picture" industry, which in recent years has absorbed a considerable proportion of the total output of the metal. Both these industries are formidable competitors for silver produced to-day, and they will have to be reckoned with by future Chancellors of the Exchequer.

Time-reckoning of the North American Indians.

UNDER the title, "Calendars of the Indians North of Mexico" (University of California Publications in American Archæology and Ethnology, vol. xvi., No. 4), Miss Leona Cope has collected and arranged a large amount of information dealing with the divisions of time in use among the Indians of North America, including much linguistic material. The term "calendar" must be taken in a very elastic sense, for the Indian's power of keeping account of an interval of time is usually limited to two or three years, and never went so far, apparently, as even to fix the number of days in a month. The only general rule seems to be a complete absence of uniformity, variations of system being found even among the most closely related groups. The basic period is naturally the lunation, indicated by an expression which is related etymologically, without exception, to the moon, and reckoned generally from new moon, but in some cases from full moon. The month is sometimes divided into "weeks" roughly depending on the lunar phases, but very variable in length and number. In general, the seasons are vaguely marked periods not directly connected with the months, though the latter are sometimes divided into a summer and a winter series. When the wide range of latitude in the area is considered, a corresponding variety of practice is natural enough. Thus it is not surprising that the Greenland Eskimo find a convenient division of the day in the ebb and flow of the tides, or that a Point Barrow Eskimo should say that there are nine "moons," and after that no moon, but the sun only. But the variations within connected groups make the study a complicated one.

This appears especially in the attempts to connect the series of months with the year. For the most part, covering the whole of the eastern and central region, there is no astronomical foundation. There is no uniformity in the time of beginning the year. In general, twelve months are recognised and are designated by purely descriptive names associated with some seasonal event. Some tribes have thirteen or even more months, but the mode of adjustment is quite crude, a month being sometimes intercalated or omitted only when a palpable discrepancy with the seasons shows the need. Only in the south-west, along the Pacific coast, and among the Eskimo of the far north is an astronomical element introduced. This takes the form of observing the winter solstice; the equinoxes, if recognised, are never used for the purpose. A particular variation in the naming of the months takes a numerical form. This occurs on the Alaskan coast and further south; only two tribes have a complete system of this kind, while a third is unique in combining numbered months with a solstitial basis. Ritual ceremonies are also represented in the names of the months among western tribes. Apparently, the Kaniagmiut Eskimo are alone in naming months from the rising of the Pleiades or Orion. Altogether the astronomical element in this complex subject is small, and the present memoir, which contains three maps representing the regional distribution of different types or systems, has its chief interest on the linguistic side and as a study of primitive culture.

Obituary.

DR. CHARLES GORDON HEWITT.

THE premature death of Dr. Charles Gordon Hewitt, Dominion Entomologist of Canada, who succumbed to an attack of pneumonia, following influenza, on February 29, is a serious loss to biological science. To an aptitude for field observation cultivated from his earliest youth, Dr. Hewitt added knowledge and skill in the latest laboratory methods. While eagerly devoting attention to the numerous economic problems which came before him, he always appreciated the necessity for constant purely scientific research. He worked, indeed, in the most favourable circumstances, and made the best use of his opportunities.

Born near Macclesfield in 1885, Dr. Hewitt passed from the local grammar school with a scholarship to the University of Manchester. After graduating with honours in zoology, he was appointed assistant demonstrator in that science, and when a new department of economic zoology was founded at Manchester, he became the first lecturer. During this period he hired a greenhouse and made an exhaustive study of the life-history of the house-fly, which formed the subject of his thesis for the doctorate. He was a pioneer in such work in this country, and his general results were eventually published in the form of a Cambridge manual. At the same time he undertook researches on the large larch saw-fly, which was ravaging the plantations of the Manchester Corporation round Thirlmere. He was also interested in the feeding habits of certain insectivorous birds.

In 1909 Dr. Hewitt was appointed entomologist to the Dominion of Canada, and at once began to organise laboratory work on the lines which he had already proved successful. He also paid much attention to the improvement of the law relating to injurious insects. Gradually his interests widened, until in 1917 he increased his responsibilities by accepting the post of consulting zoologist to the Canadian Commission of Conservation. He took an active part in the work of the Commission, and contributed several papers on the protection of mammals and birds

to its annual reports. His advice was duly appreciated and considered in framing legislation.

Dr. Hewitt was a corresponding member of the Zoological Society of London, and he received the gold medal of the Royal Society for the Protection of Birds.

By the death of SIR ROBERT MORANT at the early age of fifty-seven the Civil Service loses one of its ablest and most remarkable members. His great powers of organisation found full scope for their exercise when he was, in 1902, appointed Secretary of the recently created Board of Education. The appointment was well merited, for it was to his indefatigable industry in supplying material, to his skill in dealing with details, and to his ingenuity in overcoming difficulties that the Education Bill of 1902 was safely carried through Parliament. As permanent head of the Board of Education his restless energy and ceaseless activity bore down all opposition, and made him ready at all costs to carry out his own ideas. Organisation was indeed with him a ruling passion, and the smooth working of a complicated machine tended to become more important than the purpose the machine was intended to serve. During the ten years that he held the post of Secretary he served under five different Presidents, and the rapid succession of his temporary chiefs was not altogether unconnected with his own remarkable tenacity of purpose and skill in carrying it into effect. While his undoubted talents and magnificent powers of work have thus left their mark on the educational system of the country, it still remains to be seen if the vast and expensive machinery he called into existence will be more of a help than a hindrance in the development of our national education. In 1912, on the appointment of Mr. J. A. Pease as President of the Board of Education, Sir Robert Morant was promoted to the chairmanship of the English Commission formed under the National Health Insurance Act. He lived to see the early opposition to this Act gradually die away, and the Act itself become part of a great scheme of health legislation. To this Commission he devoted the same power of organisation and intensity of effort, and his early death is probably largely owing to his unsparing use of these great talents in the public service.—C. A. B.

THE death is announced of the veteran Italian botanist, DR. PIER ANDREA SACCARDO, emeritus professor in the Royal University of Padua. Born at Treviso in 1845, Prof. Saccardo joined the Royal Botanic Garden of Padua in 1866 as assistant director, and in 1878 became director—a post which he retained for the remainder of his official life. He was also professor of botany in the Royal University. He is best known for his systematic work on the fungi; his "Sylloge Fungorum omnium hucusque cognitorum" has been, since the publication of vol. i. in 1882, the working handbook of systematic mycology. Succeeding parts or volumes appeared at intervals, the last, vol. xxii., in 1913; other eminent mycologists have co-operated in this great work. Prof. Saccardo also published numerous separate memoirs dealing with the fungi. His "Notæ Mycologicæ" was a series of descriptive papers in various journals devoted to mycology from 1890 to 1916, when series xx. appeared in the *Nuovo Giornale Botanico Italiano*. But his activities were not limited to the fungi. Under the title "La Botanica in Italia" (1895, 1901), an exhaustive compendium of Italian botanists and their work from the Roman epoch onwards, he made a valuable contribution to botanical bibliography. In 1909 he contributed a supplemental volume to the "Flora analitica d'Italia" (by Fiori, Paoletti, and Béguinot), entitled "Cronologia della Flora Italia," a systematic list of the earlier records of the species of ferns and flowering plants, native or naturalised in Italy. Prof. Saccardo was also the author of a pamphlet, "Chromotaxia," on colour nomenclature, for the use of botanists and zoologists. In recognition of his eminent services to botany he was elected in 1916 a foreign member of our own Linnean Society.

WE regret to note that *Engineering* for March 5 records the death of MR. WILLIAM RICHARDS WILLIAMS on February 23. Mr. Williams studied engineering at the Royal Engineering College, Coopers Hill, and was appointed in 1887 assistant engineer to the Public Works Department by H.M. Secretary of State for India. His work in India was chiefly connected with irrigation. In 1901 he was appointed to the Irrigation Service in Egypt, and ultimately became Inspector-General of Irrigation, Lower Egypt. Mr. Williams had been a member of the Institution of Civil Engineers since 1906.

WE have received from Dr. Angel Gallardo, now president of the Argentine National Council of Education, a copy of his obituary notice of DR. F. P. MORENO in *El Monitor de la Educación Común* (Buenos Aires, December 31, 1919). Dr. Gallardo gives some account of Dr. Moreno's later work for education, to which we briefly referred in NATURE for January 15, and emphasises especially the importance of his efforts to provide for the children of the poorer classes. Among other institutions, Dr. Moreno established the Boy Scouts in Argentina. The notice is accompanied by an excellent portrait, which is, however, a little blurred in the printing.

WE much regret to see the announcement of the death, on March 13, in his seventy-eighth year, of PROF. CHARLES LAPWORTH, for many years professor of geology and physiography in the University of Birmingham.

The Gyrostatic Compass.

By S. G. Brown, F.R.S.[1]

I HAVE directed attention to several faults that have to be rectified if the compass is to be of use on a ship, and I shall now discuss the last, but by no means the least, of the errors that may arise if the instrument is not properly designed. This error was not known when the gyro-compass was first brought out, and it proved a most difficult fault to correct, while its elimination has had more to do with the design of the later forms of gyro-compass than any other factor.

If a gyro-wheel is precessed towards, and kept pointing to, the north by an ordinary pendulum weight, it will work well on board ship provided that the ship is steaming on a fairly smooth sea; but if the direction of the ship points anywhere in the quadrants—that is, north-west or north-east, south-west or south-east—and the ship rolls, the wheel will try to set itself so as to bring the rim of the spinning wheel in line with the roll; and in a long-continued and heavy roll the compass may show an error of 20° or more—a most serious fault, and one that would render the instrument quite useless in a heavy sea. This error is called the "quadrantal error." The extent of the error depends upon the violence of the ship's rolling and the direction of the axis of the wheel. If the ship points direct north, south, east, or west, the error is nothing, but it would be a maximum in any of the directions before mentioned.

I think Anschutz was the first to point out the error and suggest a cure. This I gather from one of his publications in the year 1911, in which, speaking of the tendency of the compass to wander when on board ship, he says:—"Theoretically, the influence of rhythmic turning movements on a gyroscopic apparatus must disappear completely if not only the real, but also the apparent, movements of inertia of the movable system become equal for each plane."

If we go back again and study our simple gyro-compass, we see that the movable system is not symmetrical. In the direction of the axis of the wheel the effect of tilting movement is more or less resisted by the spinning wheel—this may be termed the stabilised direction; while at right angles to this—that is, in the direction of the rim of the wheel—there is no resistance to tilting encountered, and this direction we term the direction of free swing. A simple form of gyro-compass pointing, therefore, in a direction, say, north-west on board a rolling ship has a force applied to it tending to turn it so as to bring its direction of free swing into line with the roll.

Anschutz gets rid of the error by multiplying the number of his gyro-wheels and by making the instrument as symmetrical as possible. In England the quadrantal error was first discovered and studied, I believe, by the Admiralty Compass Department. In the year 1914 the Sperry Co. claimed to have effected a cure for the error by attaching the pendulous weight, not directly to the gyro casing, but through a pin arranged to move in a slot in the casing. In order that the axis of suspension of the pendulum may remain vertical when the compass oscillates with the rolling of the ship, a small auxiliary gyro was employed to stabilise the pin connection between the pendulum and the gyro casing.

We therefore see in these applications of Anschutz and Sperry two general ideas. In the first case the idea is to make everything symmetrical, like a ball, so that there is no stabilised or free swing direction to the wheel, and, therefore, no tendency to turn; while in the second a method is provided to prevent the point of application of the pendulum weight from moving and acting as a crank, and, by keeping the pendulum weight always vertical in the north-west direction, to destroy its power of turning the compass. In the Brown compass the quadrantal error is eliminated by making the weight operate completely out of phase with the roll—that is, at 90° displacement.

If a gyro-compass is worked by a weight which tends to precess the wheel in phase with the roll, then there must be a quadrantal error, but there will be no error if it is forced to operate completely out of phase with it. It is also essential, as Anschutz has remarked, that the real moments of inertia shall be the same in all directions of the movable system of the compass; that is to say, the moving system should be in dynamic balance, as it is termed.

If a child's hoop is suspended by a string and is swinging in one direction, the hoop tends to set itself lengthwise to the direction of the swing. On the other hand, if an exactly similar hoop be placed over, but at right angles to, the first, and suspended as before, then on swinging the hoops there will be no tendency for them to turn, as they are now in dynamic balance. It is for this reason that the mass distribution of the moving system of the gyro-compass should be in dynamic balance, and to carry this out adjustable weights are fitted, usually in the direction of the spindle of the wheel, to counteract the weight of the supporting ring of the gyro casing, and thus there is no tendency for the compass to turn, due to this cause, when under the action of rolling.

The Brown gyro-compass is shown diagrammatically in Fig. 4. A is the gyro-wheel in its casing B. This case is carried on knife-edges M in the vertical ring F, and is thus free to tilt under the action of the rotation of the earth. The vertical ring turns in azimuth on a frictionless mounting, consisting of an oil-pump at the bottom and a ball-bearing, *m*, at the top. XY is the three-phase motor that drives the oil-pump.

The gyro-wheel is the rotor of a three-phase motor, and current is led into the moving system through the three sets of iron contact rings R and S. These rings do not touch, but the outer set are hollow, and mercury fills the space between them, so that there is little friction. The vertical ring is dynamically balanced by two projecting weights D. Q is the pendulous mounting, supported by gymbal rings and by the outer row of springs to take up shock.

The gyro-wheel runs at 15,000 revolutions per minute, and thus acts as a powerful blower, giving an air-pressure equal to some 3 in. of water. Fixed to the vertical ring, but connected through the hollow bearing M to the inside of the case, is the air-jet L. This jet blows into the two halves of the air-box K, and thence through the pipes J; the air-pressure is thus transmitted to the oil in the two sets of bottles C and D. H is another air-jet similarly mounted, and employed to act upon a pair of contact-making vanes I.

The contacts I, through the agency of the controller, which is fixed on the switchboard, are to work the repeaters and the step-by-step motor V; this motor forces round the follow-up ring N to keep the contact-making vanes I always opposite the air-jet, and in doing this all the repeaters on the ship follow suit. U is the compass card fixed to the upper por-

[1] Discourse delivered at the Royal Institution on Friday, January 30. Continued from p. 48.

tion of the vertical ring, and O the lubber-line support.

By removing the four screws marked *n* the gyro-compass can be completely removed from the gymbal rings. The instrument thus removed is shown in Fig. 5.

To explain the action of the oil bottles I have introduced Figs. 6 and 7.

Fig. 2 illustrates the simplest form of compass, in which the wheel and case B are controlled by the pendulous weight W. When the case tilts, as shown, W is moved to one side of the vertical support, and the weight tries to bring the case again to the horizontal.

Suppose the wheel revolves in the direction of the arrow *a*, the righting torque is in the direction of the arrow *b*; then the wheel and case will turn in azimuth in the direction of the arrow *e*. Such a compass would

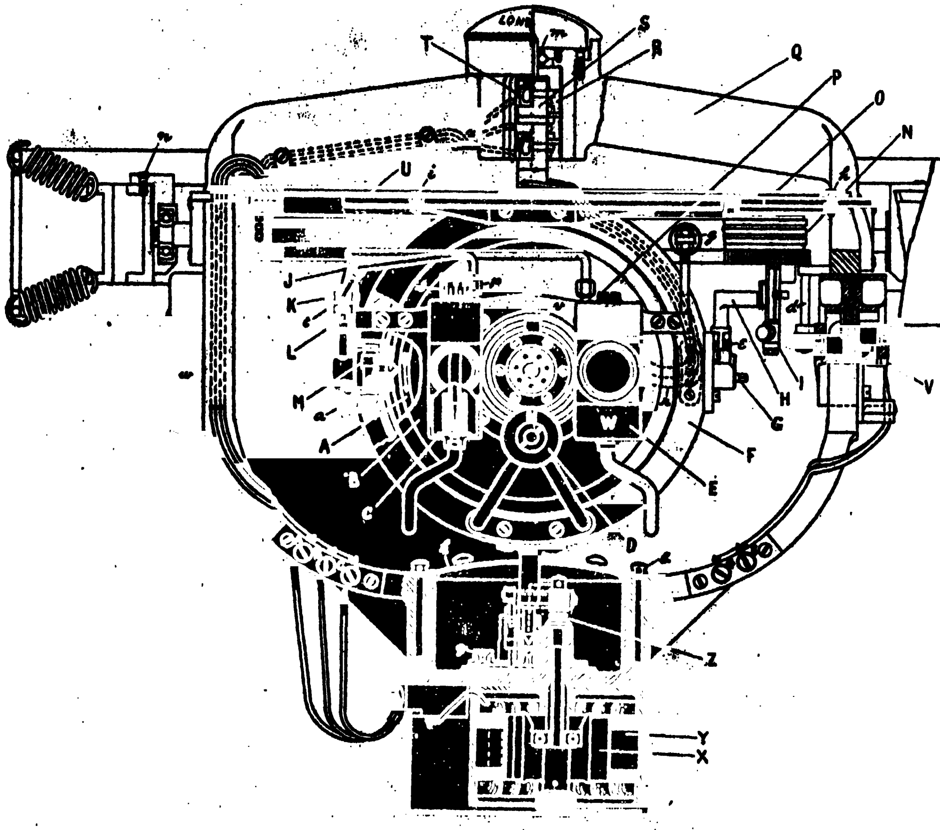

FIG. 4.

have a quadrantal error, because the weight W would produce stresses in phase with the roll.

Fig. 6 illustrates the method of control of the Brown compass. When the case B is horizontal the bottles E, E are half-full of oil, and the air-jet L is blowing equally into the two halves of the air-box K; but when the case tilts, as shown, then the air-pressure blows into one side of the box more than into the other, and in such a direction as to force the oil from the lower bottle into the one raised. There is, therefore, a considerable righting torque indicated by the weight of the oil W trying to restore the case back again to the horizontal.

When the pendulum swings under the action of the rolls of the ship, the air-jet L moves from one side to the other of the air-box in tune with the roll, blowing the oil periodically from one bottle to the other. At the middle of swing of the pendulum the air-jet is at the middle of the air-box, and there is no difference of air-pressure, and, therefore, no movement of the oil; and when the swing is at the end of its path, and not moving, the air-jet is at one side of the air-box and producing the maximum movement in the oil; it will therefore be seen that the movement of the pendulum and that of the oil are out of phase with each other. It is for this reason, given good dynamic balance, that there is no quadrantal error whatsoever with this method of control.

Fig. 7 illustrates the method of damping the compass. Fixed to the same air-box K are the two damping bottles C, C, smaller than E, E, but the air here acts in the opposite direction to that in Fig. 6.

In one of these damping bottles is the adjustable needle-valve, and this valve has a constricted passage, and thus the flow of oil from one bottle to the other is suitably retarded.

As regards the accuracy of the compass, I may mention that one on board a flagship in the North Sea during the war was observed with particular care, especially during very heavy weather, and it was reported that it was never more than $1\frac{1}{2}^{\circ}$ from the true north position during the whole of the tests.

Trials on a commercial ship have demonstrated the fact that the employment of a gyro-compass resulted in the ship steaming every day more than 3 per cent. greater mileage; in other words, one day's steaming in thirty would be saved, resulting in a proportionate saving in coal and all other expenses.

I come now to a most important application of the gyro-compass, namely, its employment as a gun director.

The use of the gyrostat in the Whitehead torpedo has revolutionised naval strategy, and I believe the use of the same instrument in the form of a gyro-compass gun director may possibly produce profound changes in gunnery practice in the future.

Modern naval warfare is entirely different from that of the past in the fact that the rival fleets come into action when separated by many miles; the guns have, therefore, to be worked and fired while the distant targets are invisible to the gunners.

The guns have to be directed by observers in an elevated position, these observers communicating the distance of the target and its direction in space.

The direction in space must be supplied by a gyro-compass on board the ship, and it is essential that the compass for this purpose should be of extreme accuracy.

Once the guns are properly trained, they may be joined up and controlled by the gyro-compass, and for this purpose the turrets would be designed to act as huge repeaters, keeping the guns pointing on the target, changing only on receiving new directions from the observer.

The compass would hold the guns pointing on the distant target quite independently of the movements of the ship, which may at the time be steaming at full speed and manœuvring. Such movements are a great protection to ships against submarine and aerial attack.

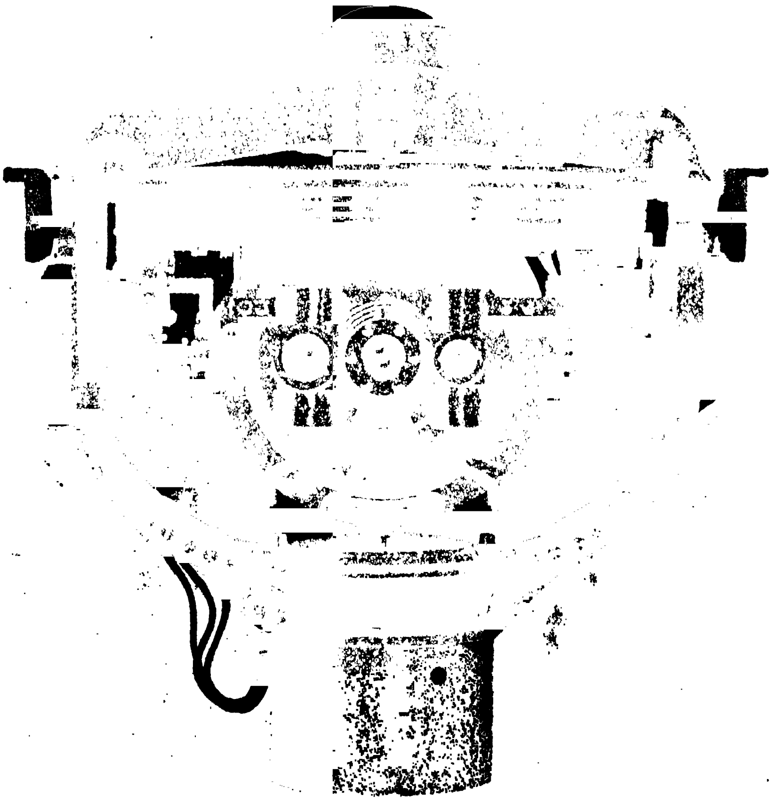

FIG. 5.

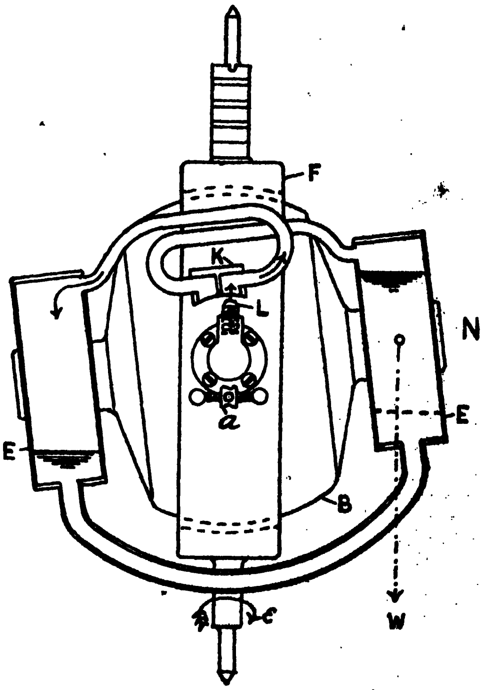

FIG. 6.

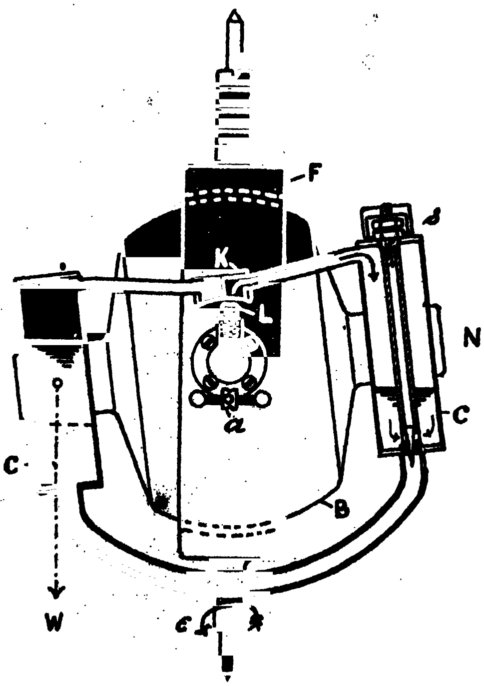

FIG. 7.

It has been suggested that the day of the big battleship is over, but I am doubtful of this, as I understand that ships can be made proof against ordinary submarine attack by means of blisters filled

with oil, as in our Navy, or by coal-dust, as used by the Germans.

Working the guns with the ships at full speed, as I have just stated, will be an additional protection, while submarine craft will be more dangerous operating against fixed objects, such as harbour defences, etc., in which case they could be detected from the shore by submarine listening devices, such as my liquid microphone.

In closing this discourse, I should like to say that a good deal of credit is due to Anschutz for the courage he displayed in being the first to attempt a gyro-compass, knowing as he did the extremely feeble force that is likely to result from the earth's rotation, and in the fact that the instrument must be carried on a rolling, pitching, plunging vessel. With us who follow it is a question over again of Columbus and the egg. For myself, if I had known at the commencement of my acquaintance with the gyro-compass—some five years ago—all the difficulties that had to be encountered, I think I should have abandoned the pursuit.

Notes.

AT the meeting of the Royal Society on June 3 the Bakerian lecture will be delivered by Sir Ernest Rutherford on "The Nuclear Constitution of the Atom."

SIR JAMES DEWAR has been elected a corresponding member of the French Academy of Sciences in the section of general physics in succession to the late Prof. P. Blaserna.

THE Institute of Research in Animal Nutrition at Aberdeen has received a gift of 10,000*l.* from Mr. J. Q. Rowett. The amount required from public sources for the establishment of the institution is 25,000*l.*

MR. A. A. CAMPBELL SWINTON, during his presidential address to the Wireless Society of London on February 28, reviewed, with the aid of experiments, advances in wireless telegraphy since 1914, and received, in full view of the audience, messages from Gen. Ferrié in Paris and from the Slough station of the Radio Communication Co. These messages were received, not on the usual external aerial, but on a simple loop of wire standing on the lecture-table.

IN the course of a speech at a Conference of Provincial and Suburban Wireless Societies, held on February 27 under the presidency of Sir Charles Bright, Capt. F. C. Loring announced that the Post Office is in favour of granting wireless licences of about 10 watts where an amateur can prove that he thoroughly understands the apparatus and is a proficient operator, and that his transmitting station is to be used for genuine experimental work and not merely for communication between other stations in a general way.

WE are officially informed that Dr. Carlos Ameghino has been appointed director of the National Museum of Natural History, Buenos Aires, in succession to Dr. Angel Gallardo, who retired in 1916 to become Minister of Education. The new director is the younger brother of the late Dr. Florentino Ameghino, the distinguished palæontologist, who held the same office from 1902 until his death in 1911. During the earlier part of his career Dr. Carlos Ameghino explored many parts of Patagonia and made the great collections of fossil vertebrate remains which were studied and described by his brother. During recent years he has been interested in the evidence for the association of man with extinct mammals in Argentina.

THE council of the Linnean Society has issued to the fellows a statement of the present financial position and outlook of the society, recommending them to increase the annual contribution from 3*l.* to 4*l.* The cost of publication is now so high that the Transactions have already been suspended, and the Journal is so much reduced that the issue of many valuable papers has to be postponed for an indefinite time. The due maintenance of the library and the preparation of an up-to-date catalogue are impossible in existing circumstances, and all establishment charges still tend to rise. If the difficulties appeared to be temporary some of the small invested funds of the society might be used, but as there is no prospect of a return to former conditions an increased income is absolutely essential. Nearly all the learned societies are at present faced with similar problems, and the time seems to have arrived when there should be some action in common to consider the possibility of help from public funds.

THE following are among the lecture arrangements at the Royal Institution after Easter:—Major G. W. C. Kaye, two lectures on recent advances in X-ray work; Prof. Arthur Keith, four lectures on British ethnology: The Invaders of England; Major C. E. Inglis, two lectures on the evolution of large bridge construction; Mr. Sidney Skinner, two lectures on (1) Ebullition and Evaporation, (2) The Tensile Strength of Liquids; Mr. R. Campbell Thompson, two lectures on (1) The Origins of the Dwellers in Mesopotamia, and (2) The Legends of the Babylonians; Mr. A. P. Graves, two lectures on Welsh and Irish folk-song (with musical illustrations); Prof. W. H. Eccles, two lectures on the thermionic vacuum tube as detector, amplifier, and generator of electrical oscillations; Prof. Frederic Harrison, two lectures on (1) A Philosophical Synthesis as Proposed by Auguste Comte, and (2) The Reaction and the Critics of the Positivist School of Thought; and Prof. J. H. Jeans, two lectures on recent revolutions in physical science, (1) The Theory of Relativity, and (2) The Theory of Quanta (the Tyndall lectures). The Friday evening meetings will be resumed on April 16, when Prof. J. A. McClelland will deliver a discourse on ions and nuclei. Succeeding discourses will probably be given by Prof. H. Maxwell Lefroy, Prof. F. O. Bower, the Right Hon. Lord Rayleigh, Prof. Karl Pearson, Prof. J. A. Fleming, Prof. W. L. Bragg, and other gentlemen.

ONE of the Industrial Research Associations formed in connection with the Department of Scientific and Industrial Research is the British Empire Sugar Research Association. If the association plans its

work on a sufficiently large scale, and raises 5000*l.* a year from the trade for five years, grants of the same amount and for the same period will be made from State funds. The offices of the association are in Evelyn House, 62 Oxford Street, W.1. The objects of the association are to establish, in co-operation with the Department of Scientific and Industrial Research, an Empire scheme for the scientific investigation, either by its own officers or by universities, technical schools, and other institutions, of the problems arising in the sugar industry, and also to encourage and improve the technical education of persons who are or may be engaged in the industry. A survey is being made of the field of research which is likely to be beneficial to the industry, and it is proposed to establish a bureau of information to which any member of the association can apply for assistance. In the first instance, the whole of the research undertaken will be carried out in existing institutions, and it will be necessary to enter into agreements with the bodies controlling these institutions for the use of laboratories and the services of skilled scientific investigators. With regard to the actual production of sugar, experiments on the cultivation of the sugar-cane and of the sugar-beet will be undertaken in suitable parts of the Empire. In this connection it is hoped that very close relations will be established with Colonial Agricultural Departments. The organisation and general supervision of the research work will eventually be entrusted to a director of research, and it is hoped to establish a Central Sugar Research Institute if and when it becomes necessary.

In Algeria most gun-owners are able to trim roughly the flints they require for the long-barrelled muzzle-loading guns and pistols which still form the principal armament of the nation. Mr. M. W. Hilton-Simpson, while engaged in collecting specimens for the Pitt-Rivers Museum, Oxford, came across a specialist who trimmed flints for sale. This worker's methods are fully described in the March issue of *Man*. He employed a rough stone for striking the flakes from the cone, and for trimming the flakes thus struck off he used a small tool resembling in outline the universal general-utility implement of the country, a combination of a hoe and pick. This man's features indicate an infusion of negro blood, but flint-chipping does not seem to be a special negro trade, the man being a resident of one of the oases where there is a negro strain in the population.

Of the eighteen species of ground-squirrels found in the State of California, four, inhabiting cultivated areas, have become pests. The life-histories of these four and of the harmless species have been very carefully described by Messrs. Joseph Grinnell and Joseph Dixon in vol. vii. of the Monthly Bulletin of the State Commission of Horticulture. In one district infested by the Oregon ground-squirrel the authors estimated that there were 112 adults to the acre or 70,000 to the square mile, and that these would consume in one day more than two tons of green forage, which would be sufficient to feed ninety head of cattle during the same time.

Bird-lovers will read with no small pleasure Mr. J. H. Gurney's ornithological notes from Norfolk for 1919 in *British Birds* for March. Perhaps the most interesting of these notes are those referring to the bittern, which seems to be returning to the Broads in increasing numbers to breed. It is satisfactory to learn that, so far as can be ascertained, this year no nests were raided, though in one nest the brood, unfortunately, died. The little owl, he tells us, which up to 1914 was confined to a few districts in the west of the county, is quickly spreading throughout the whole of Norfolk. The prevailing prejudice against this bird he considers scarcely to be justified, since "the test of dissection is rather in its favour than otherwise." During the war vast quantities of a tar-like substance were spread over much of the North Sea for military reasons. One would have imagined that the need for this had now ceased, but in these notes are records of numerous divers and guillemots picked up in an exhausted condition owing to this compound clogging the plumage.

In the fourth part of his study of the Malacostracous Crustacea obtained by the *Ingolf* and other Danish expeditions from deep water in the seas round Iceland and South Greenland ("The Danish *Ingolf* Expedition," vol. iii., part 6, Copenhagen, 1920), Dr. H. J. Hansen describes the Cumacea and Phyllocarida. Of the former group no fewer than sixty-six species are enumerated, of which twenty-four are new—a surprisingly large proportion of novelties in view of the attention that has been given by G. O. Sars and others to the Cumacea of northern waters. Together with Dr. Hansen's previous memoirs on the Isopoda and Tanaidacea, this report serves to bring into prominence both the extraordinary richness of the micro-fauna of the sea-bottom and the imperfection of our knowledge of it even in the better-known regions of the ocean. From the point of view of systematic zoology, if not also from that of marine bionomics, a one-sided impression is apt to result from confining attention mainly to the more easily studied species of the plankton. In dealing with the Phyllocarida Dr. Hansen is able to throw new light on the structure of the limbs and mouth-parts of the long-known and much-studied Nebalia.

In the March issue of *Medical Science: Abstracts and Reviews* (vol. i., No. 6), one of the reviews is devoted to the subject of typhus fever. Owing to the war this disease has been very prevalent in Europe during the last four years; for example, in Poland 124,620 cases were recorded between January 1 and July 27, 1919. Lice are the agents by which the disease is transmitted, but the causative micro-organism is still unknown. The blood-serum gives agglutination with a Proteus bacillus, the Weil-Felix reaction, which is of considerable value for the diagnosis of the disease.

An interesting lecture on the history of electrotherapy by Dr. W. J. Turrell is published in the *Archives of Radiology and Electrotherapy* for February (No. 235). In England electrical treatment appears to have been first practised by the clerical profession.

In 1756 a book on the subject was published at Worcester by Richard Lovett, a lay clerk at the cathedral, in which he records the treatment of a number of diseases with electricity. In 1780 John Wesley, the great divine, anonymously published a book entitled "The Desideratum; or, Electricity made Plain and Useful." In this he appeals to the medical profession for a trial of the curative effects of electricity, and records many alleged cures.

We have received the first number of a new British journal devoted to pathology, entitled the *British Journal of Experimental Pathology*. It is published bi-monthly under the editorship of a board of editors by Messrs. H. K. Lewis and Co., the annual subscription, post free, being 2*l*. The journal has been founded for the publication of original communications describing the technique and results of experimental researches into the causation, diagnosis, and cure of disease in man. Among the contributors to this first number are Prof. Bayliss ("Is Hæmolysed Blood Toxic?"), Dr. Cramer ("On Sympathetic Fever and Hyperpyrexial Heat-stroke"), Prof. McIntosh and Mr. Smart ("Determination of the Reaction of Culture Media"), and Mr. Fildes ("Serological Classification of Meningococci"). The journal is well produced, and will, we believe, fill a lacuna in the means of publication of research work at the disposal of British pathologists.

Mr. W. L. George, who gave evidence before the National Birth-rate Commission, has contributed to the *Fortnightly Review* for March a summary of the arguments he presented to that body, which does not appear yet to have arrived at a conclusion upon them. The line he takes is that a high birth-rate corresponds with a low degree of education, a low level of comfort, and poor foreign trade. He views, therefore, with calmness, and, indeed, with satisfaction, the recent decline in the birth-rate, and would take active steps in that direction by promoting the understanding of contraceptives and other preventive measures. Whether this could be done without leading to grave evils may be doubted. At any rate, Mr. George is justified in opposing proposals tending in the other direction, such as those for the endowment of motherhood, which would have the effect of encouraging imprudent marriages or illicit connections, and, as they involve an expenditure that he sees is financially impossible, must fall to the ground. He would have us base our quest for national prosperity on good births rather than on more births, on quality rather than on quantity. Like all difficulties that arise out of the passions and the instincts of mankind, the problem is soluble only by an appeal to reason and by a gradual education of the will in men and women. It should be noted that large families have given to the community many valuable members.

A supporting expedition for Roald Amundsen's trans-polar voyage has been organised by the Norwegian State. Some details from Scandinavian sources are published in *La Géographie* (vol. xxxiii., No. 1). The expedition which reached Greenland last summer is in charge of Lieut. G. Hansen, a Danish naval officer who accompanied Amundsen in the voyage of the *Gjoa* in 1903–5. Lieut. Hansen is now wintering at Etah, in about 78° 15′ N. This month he hopes to leave with a dozen sledges for Cape Colombia, the most northerly point of Grant Land, in 83° N. Stores and provisions for a year will be taken. Amundsen, who proposes to leave his ship, the *Maud*, at the most northerly attainment of its drift, is expected to make for Cape Colombia, and may arrive there in March, 1921.

At a meeting of the Royal Geographical Society on March 8, a paper was read by Miss E. M. Ward on "The Evolution of the Hastings Coast-line." We can scarcely agree that the Wealden dome stretches from Beachy Head to the North Foreland, as it does not extend beyond the Warren at Folkestone, where the chalk of the North Downs comes down to the sea, or that the North Foreland is in the Channel, as we might be led to believe. It may be pointed out that the eastward-flowing drift of flint beach is general on the South Coast, and that this has resulted in most of the southern-flowing rivers being turned to the east, whilst forming a spit of beach on the seaward side of the stream, this being the result of the conflict between the eastward-flowing tide and the southward-flowing stream. As the streams lost their velocity and carrying power they deposited their silt, and finally the conflict between sea and mud ended in the victory of the former, when the sea made its bold attack on the land, which is still going on, and against which engineers are fighting. The existence and continued growth of Dungeness have never yet been satisfactorily accounted for, but there is some reason to believe that the destruction of the Hastings headland let loose vast quantities of beach which had accumulated on its western side, and that this gave rise to the various low terraces still to be observed on the west side of the Ness. Miss Ward finds it difficult to believe that at Hastings there was a promontory in Neolithic times even so much as seven miles in length, but it is fairly generally believed that the passage between England and France was comparatively narrow in those times, and Prof. Boyd Dawkins even suggested that Neolithic man came across on dry land.

In the Proceedings of the American Academy of Arts and Sciences (vol. lv., December, 1919), Messrs. George F. McEwen and Ellis L. Michael deal with the functional relation of one variable to each of a number of correlated variables when the representation by linear regression is unsatisfactory. The basal idea is to assume that the dependent variable may be represented by a sum of functions of the independent variables, and to determine these functions by dissection of the material into a series of groups. If, for instance, a variable w is to be expressed in terms of x, y, and z, a series of groups of (w, x), (w, y), and (w, z) are formed; a first approximation to the relation between w and x is obtained by taking the averages of the (w, x) groups; corrections are then derived from the averages of the (w, y) and (w, z) groups; from the second approximations third approximations are derived, convergence being ob-

tained to the values of w corresponding to variations of x alone. Similarly the other functional relations are obtained. The idea of defining a function by means of a series of corresponding values has been utilised by various mathematicians; the most obvious criticism of its statistical applicability is that an immense amount of arithmetic would be required to determine more than a very small number of corresponding values. The method, however, deserves further consideration.

THE *Meteorological Magazine*, an official publication of the Meteorological Office, was first issued under its new title about the middle of February. The journal incorporates *Symons's Meteorological Magazine* and the *Meteorological Office Circular*. For convenience in reference, the serial numbers of *Symons's Meteorological Magazine* are being carried on. The change has come about through the absorption of the British Rainfall Organization in the Meteorological Office. The cover of the new publication gives the portraits of four pioneers of meteoro-logical Office. Of these Admiral FitzRoy had charge of the Office at its initiation, when it was a branch of the Board of Trade, and Mr. Symons was an assistant sixty years ago, but left after a short period and devoted himself to the collection of rainfall returns, from which evolved later the British Rainfall Organization. Gens. Sabine and Strachey were successively chairmen of the Meteorological Office when controlled by the Royal Society. Little change has been introduced into the style and character of the publication, and it is evidently not intended to make any radical alteration. In addition to the interesting article on "Weather in the British Isles" for the preceding month, which has hitherto regularly appeared in *Symons's Meteorological Magazine*, an article is now given on "Weather Abroad" which will doubtless be valued by readers of the journal.

ON March 10 Lord Moulton delivered a lecture at University College on "The Training and Functions of the Chemical Engineer." The lecture was presided over by H.R.H. Prince Arthur of Connaught. Lord Moulton referred to the great importance of securing an adequate and suitable training for those who had to perform chemical operations on a large scale. In a research chemical laboratory work is carried out on small quantities of pure substances with every convenience at hand and regardless of cost and economy. In chemical industry, on the contrary, it is necessary to carry out operations on vast quantities of impure substances with no conveniences and with the greatest possible regard to the matters of cost and economy. The question of change of scale was all-important, since it was extremely difficult to secure on a large scale that uniformity of conditions easily obtained in a research laboratory and fundamental for the success of the operation. Lord Moulton laid great emphasis on the subject of costing and costs, since, as he pointed out, the success of an industrial operation in the real world of chemical industry, as compared with the success of a chemical operation in the ideal world of the research laboratory, depended entirely on its cost. It was a noble and dignified business to make things cheaply so that they could be utilised by large numbers of people. In conclusion, Lord Moulton referred to the fact that the Ramsay Memorial Committee had given 25,000*l.* for the building of a laboratory of chemical engineering at University College. He earnestly hoped that the further sum of 50,000*l.* which was required would be forthcoming. A vote of thanks to Lord Moulton for his interesting lecture was proposed by Prof. F. G. Donnan, who referred to the great work Lord Moulton had done during the war as Director-General of the Explosives Supply.

Mr. James Thin, 54 South Bridge, Edinburgh, has just issued a useful and comprehensive catalogue of new and second-hand books on technical and scientific subjects. The prices named in the second-hand section are very reasonable. A laudable feature of the catalogue is the giving of the dates of publication of the volumes.

THE *Oxford University Press* will shortly publish an English rendering, by H. L. Brose, of "Space and Time in Contemporary Physics: An Introduction to the Theory of Relativity and Gravitation," by M. Schlick, with an introduction by Prof. F. A. Lindemann. The work is intended for the general reader. It deals with the problem of the structure of cosmological space, discusses the relation of psychological to physical space, and analyses the significance of measurements in physics.

THE *Reader's Index*—a bi-monthly magazine issued by the Croydon Public Libraries—for March and April contains much useful guidance for readers, including a reading list of books and periodical articles on the Einstein theory. We notice references to articles in NATURE of June 11, 1914; December 28, 1916; March 7 and 14, 1918; November 13, 1919; and December 4, 11, and 18, 1919.

A NEW series of books dealing with the textile industries has been arranged for by *Sir Isaac Pitman and Sons, Ltd.* The editor will be Prof. R. Beaumont, and one of the first volumes in the series to be published will be that by the editor on "Union Textile Fabrication," which will contain three main divisions dealing respectively with bi-fibred manufactures, compound-yarn fabrics, and woven unions. Another volume in the series will treat of "Flax Culture and Preparation." It will be the work of Prof. F. Bradbury.

MR. D. N. WADIA writes to say that the two illustrations from his "Geology of India" reproduced in NATURE of January 15 were not his own photographs, but from the collection of negatives at the offices of the Geological Survey at Calcutta. Acknowledgment of this was, unfortunately, omitted from the book, and our reviewer assumed, therefore, that the photographs were the author's.

Our Astronomical Column.

THE TOTAL SOLAR ECLIPSE OF SEPTEMBER 20, 1922.—Mr. A. R. Hinks read a paper at the meeting of the Royal Astronomical Society on March 12 on the conditions along the track of totality in this eclipse. The nearest available station is in the Maldive Archipelago, where the sun's altitude is 34½° and duration 4m. 11s. It is recommended that an uninhabited islet be selected, as there is less risk of illness on one of these, the others having a bad reputation for Europeans. Also it should be an islet in the centre of a lagoon, as the outer ones experience vibration from the surf, which would spoil fine definition. The weather is likely to be clear but windy.

Christmas Island, south of Java, is near the noon point; the sun's altitude is 78½° and the duration 3⅓m. at the south point of the island. There are a flourishing phosphate industry on the island, a monthly steamer from Singapore, and good jetties and cranes at Flying Fish Cove, whence there is a railway to the south coast. Much of the island is covered with forest (haunted by large land-crabs), so some clearing might be necessary to give enough sky room for adjusting the equatorial mounting which it is intended to use here. The weather conditions in September promise to be very good.

The west coast of Australia offers difficulties, the country being barren, and there being no port in the neighbourhood of the track. The east end of the track in Australia is in Queensland, just south of Brisbane. The sun's altitude here is only 18°, but it is possible to obtain an altitude of about 26° by travelling by rail into the interior.

The programme will include a repetition of the investigation of the Einstein shift; there is a fair field of stars round the eclipsed sun, though they are much less bright than those of the eclipse of May, 1919.

THE BINARY STAR p ERIDANI.—This southern binary star (R.A. 1h. 36m. 45s., S. decl. 56° 36′) was first noted as double by Dunlop in 1826, and observed by Sir John Herschel at the Cape, 1834 to 1836. It was for some time doubtful whether the relative motion was not rectilinear, but curvature is now definitely established. Mr. B. H. Dawson gives a determination of the orbit in the *Astronomical Journal*, No. 762, as follows:—Period 218·9 years, T 1806·14, e 0·721, a 8·025″, ω 301·40°, i ±114·26°, ☊ 1·03°. There is still much uncertainty, as only one quadrant has been observed. The large size of a makes the pair an interesting one. Apastron was passed in 1916, and the stars are now 9″ apart. Both are of magnitude 6·2; the proper motion of the middle point between them is +0·0336s., +0·022″, according to Boss.

FAINT NEBULÆ.—Publications of the Yerkes Observatory, vol. iv., part 2, is occupied with an account of a research on faint nebulæ by Mr. Edwin P. Hubble. Mr. Hubble took a series of photographs, with the 24-in. reflector at the Yerkes Observatory, of some rich nebulous regions, including seven well-defined clusters, containing more than five hundred nebulæ. The measures for ascertaining their positions are given, but, owing to the bad figure of the images in the outer parts of the field, the precision is not considered very great. The exposures did not generally exceed two hours, as beyond that point very little seemed to be gained. The average diameter of the nebulæ is about 25″, but in certain regions, notably in Perseus, they are distinctly smaller, about 15″. The question of the distance and status of these small nebulæ is discussed at some length, but the evidence appears to be insufficient to decide whether they are in the remoter parts of the galactic system or altogether outside it.

International Fishery Investigations.

THE first meeting since the autumn of 1913 of the International Council for the Exploration of the Sea took place in the Surveyors' Institution, Westminster, on March 2–6. The Council exists "to consider and conduct investigations into the fisheries of the North Atlantic; to examine how far these fisheries are being depleted by fishing; to investigate natural methods, such as by breeding, etc., of keeping up the stock; and in cases of certain future failure of supply to suggest the necessary remedial measures. The Council has been conducting researches for nearly twenty years, but its operations during the war were brought almost to a standstill. For the most part it deals with the sea-fish common to all countries, but a special sub-committee considers the salmon, and a second the eel; shellfish are not investigated. The countries represented were France, Belgium, Holland, Denmark, Sweden, Norway, Finland, and Great Britain, each country having two delegates, with scientific experts from the fishery authorities of each. France was represented for the first time, but Germany and Russia dropped out of representation; the meeting was too hurriedly convened to allow of the U.S. Congress appointing delegates, and there was no representative of Canada, the eastern fisheries of which are mainly coastal. Great Britain was represented by Mr. H. G. Maurice and Prof. D'Arcy Thompson as delegates, Mr. Holt representing Ireland, while most of the scientific staffs of the three countries took part in the deliberations of the committees, including Prof. Stanley Gardiner (temporary Director of Fishery Research) and Comdr. Jones (of the Scottish Office).

March 2 was devoted to general business and the formation of committees, the whole body meeting together under the chairmanship of Prof. Petterssen (Sweden). After a telegram of respectful homage had been dispatched to the King, the chairman referred in sympathetic terms to the troubles of the last years and to the increased importance to Europe of safeguarding its supplies of fish. Commodore Drechsel (Denmark) and others spoke of the closure of the greater part of the North Sea as the most gigantic scientific experiment ever made in respect to the closure of areas, and one from which we might be able to draw the most important deductions in respect to the conservation of our fish supply. Mr. Maurice pointed out the difficulties under which all countries are at the present time labouring, and appealed to all to help in drawing up practical programmes of work such as each country could guarantee to carry out. The meeting then split into two committees for fishery investigations and fishery statistics and for hydrography and plankton (floating life in the sea).

The committees met twice daily during the next three days to draw up their programmes to be submitted on Saturday, March 6, to the whole body of delegates. The main deliberations of the Fish Committee were in respect to the plaice. All were agreed that the fishery statistics of Western Europe up to 1914 proved that there had been a most serious depletion of the stock of plaice on the fishing-grounds of Western Europe, particularly in the southern half of the North Sea. The apparently probable disappearance of this fish, from the point of view both of the industry and of the consumer, was felt to be so calamitous that even the strongest measures were thought to be justifiable. It was proposed that the Council should suggest to the diplomatists to negotiate a size-limit and the permanent closure of certain areas to provide a reserve, from which the young plaice might spread so as to restock the open grounds. It was pointed out that Denmark had already insti-

tuted a size-limit of nearly 10 in., but that Holland did not favour one of more than about 8 in. The representatives of Great Britain considered that the effect of the closure of areas on the industry had not been sufficient studied; that the closed areas must be as small as possible, consistent with the preservation of the plaice stock of the North Sea; and that the study of the effect of the war in having closed great areas would materially assist the Council in arriving at the most practical results.

The British view was finally adopted, and it was decided to undertake a year's intensive plaice investigation with the view of considering the whole question in 1921 and making recommendations. The committee then proceeded to draw up a programme of investigations. A thorough collection of statistics of plaice marketed was deemed essential. Furthermore, an accurate knowledge of the sizes of the fish both as marketed and as caught on commercial trawlers was recommended. The liberation after marking of a series of fish would be necessary to show their wandering during the year. Further experiments in the liberation of marked fish of small size on the Dogger Bank were recommended. The spawning-grounds should be more fully investigated and charted. The liberation of a large series of drift-bottles, both surface and bottom, was deemed essential so as to ascertain the drift of the eggs and young larvæ which float for many weeks in the water. The examination of numbers of eggs so as to ascertain the intensity of spawning in different areas was deemed advisable, as well as an investigation into the food on which the larvæ feed.

As most of the spawning areas of the plaice are off the east coasts of Great Britain, it was generally recognised that this country would have to concentrate in the present year mainly on these plaice investigations, but the hope was expressed that the examination of the life-history and wanderings of the lemon-sole would not be neglected, while the other fish occupying plaice grounds should be carefully recorded. The continued examination of the constitution of the herring shoals and of the other work on the life-history, growth, etc., of the herring was recommended, Great Britain being requested to collect samples and to send them to Norway, the representatives of which (Dr. Hjort, Prof. Gran, and Dr. Lea) undertook to examine them.

The Danish representatives described their plans for a second great expedition in the North Atlantic to search, among other objects, for the spawning-grounds of the fresh-water eel, which their previous work showed to be somewhere in the latitude of Madeira and at depths of at least 1000 or 1500 fathoms. They also gave an account of the commercial results obtained by the importation of the young eels (elvers) and their liberation in Danish rivers and lakes. Dr. Johansen (Denmark) and Dr. Rosen (Sweden) described the work of their respective countries on the movements of salmon and sea-trout, the ages of these fishes for spawning, the liberation of fry, etc., showing results of considerable economic importance—results capable of immediate application in many British rivers could the difficulties in respect to pollution be overcome.

The Hydrographical and Plankton Committee divided into sub-committees for its two subjects. The former is mainly concerned with the currents on the fishing-grounds in respect both to the movements of such fish as herring, mackerel, and pilchards, and to the drifting of fish-eggs and young. It was generally considered that the hope of foretelling the movements of the fish and the success or otherwise of the spawning year by year depended on a more extensive study of the movements of Gulf Stream waters from Barents Sea to Iceland and down the European coasts to Mogador, with more intensive investigations in the North Sea. The nature of the spawning was deemed peculiarly important, as on this depends to a large degree the success of the fishing some years afterwards when the spawn has grown into fish of marketable size. Extensive temperature records and water samples from a series of transoceanic liners month by month were recommended, and the hope was expressed that the United States would co-operate by collecting samples on liners cutting the Gulf Stream nearer where it leaves the Straits of Florida.

A full programme of hydrographic work was recommended in the southern half of the North Sea in view of the plaice investigations. Here the sea is so shallow that the water is thoroughly churned up from surface to bottom, and, in consequence, surface samples only, mostly from passenger ships, were proposed. The drift-bottle programme was approved and somewhat extended in the hope of understanding better the isobaric, temperature, and salinity charts of the region in respect to the movements of fish, with the view of making them usable by fishermen.

The plankton sub-committee, under Prof. Gran, drew up a very small programme on account of present difficulties, but it decided to recommend researches on the physico-chemical conditions of sea-water in respect to the life in the sea. It regarded this basal research as impossible either to initiate or carry out under the Council, and so decided to record its opinion as to the necessity of such researches on living animals in respect to the water in which they live. It was pointed out that the acid or alkaline nature of the water affects the rate of growth of young fish, and that further knowledge here in respect to trout, salmon, and plaice might become at once of economic importance. Animals, too, show growth in the most carefully filtered sea-water—a matter of the greatest importance, the meaning and utility of which could not be foretold. It is well known that the blood of human beings can be replaced by sea-water, but not so effectively by artificial sea-water, which is made from distilled water by dissolving in it the various salts. The possible meaning of this was discovered by Dr. Allen (Plymouth) working on minute marine animals, and points to those mysterious substances "vitamines," of which so much has been heard in the last six years and so little is known. The searcher for economic results in fisheries must have the basal theory and knowledge in respect to his living fish duly developed as the foundation on which he has to build. Incidentally, an increase in knowledge of this soluble food, etc., should be rapidly applicable to oyster- and mussel-farming, and the sub-committee could only hope that the requisite genius to give further ideas would soon be found.

The development of lakes and rivers for the production of food was of special interest to Mr. Holt (Ireland), the Swedish and Finnish representatives, and Dr. Redeke (Holland), the last giving an account of the very great development of the fresh-waters of his country. So far as fish were concerned—salmon is treated separately—the subject is of little importance to Great Britain, but the possibility of the development of a button industry by the cultivation of mussels was thought worthy of investigation.

France was represented by M. Kersoncuf (Director of Marine Fisheries), accompanied by M. Tissier, Prof. Behal, Prof. Joubin, and Dr. le Danois. A meeting with the English and Irish representatives resulted in the formation of a special committee to consider and report as to fisheries off the mouth of

the English Channel and in the Bay of Biscay and to the west and south. The chief fish of this region are the migratory mackerel and pilchard and the hake, which apparently is a great wanderer. It is hoped also to investigate the possibilities in respect to tunny, of which there should be an almost unlimited supply in the Atlantic. France undertook the preparation of a fishing chart of certain grounds, Ireland particular cruises to meet the French vessel, and England to continue and extend her investigations into the waters of the Channel. England was also asked to undertake, as soon as possible, regular cruises to the south-west to investigate the approach of the Gulf Stream waters in respect to mackerel, pilchards, and tunny.

At the full meeting on Saturday, March 6, the programmes of the committees were adopted, and Mr. H. G. Maurice was unanimously elected president for the ensuing year, the next meeting to be held in Copenhagen in 1921. The present writer believes that the fishery industry appreciates the vital importance of these very technical investigations, in the results of which the interests of the fisherman and the researcher are identical; he appeals to the industry to co-operate in every way in its power, and in particular to return drift-bottles and marked fish.

Exhibition of Diseases of the Para Rubber-tree.

AN important exhibition illustrating the fungal diseases to which the Para rubber-tree (*Hevea brasiliensis*) is subject in Ceylon and Malaya was opened on March 10 in the Botany Department of the Imperial College of Science and Technology by the Marquess of Crewe in the presence of leading representatives of the rubber trade. The exhibition, which has been organised by Prof. J. B. Farmer, Director of the Biological Laboratories of the college, includes a large number of trunks of rubber-trees, specially shipped from the East, showing the diseases as they occur in the plantation, and forms a striking commentary on the optimism which obtained in the first years of the industry as to the probable relative immunity of Hevea from disease.

The warnings issued by botanists at the time that the Para rubber-tree would no more escape epidemic fungal disease than any other crop plant has, unfortunately, been justified by events. At the present time there are several diseases which, if not checked as the result of sound scientific knowledge, intelligently applied, may seriously affect the future of the plantation industry. The former optimism finds a present-day counterpart in the equally dangerous view held in certain quarters that "sanitation" is all that is necessary as a safeguard against disease, and that, in consequence, expenditure on mycological research is waste of money. The fact that the causative organism (if organism it be) of the most dangerous disease in the plantations at the present time ("brown bast") is as yet unknown is sufficient reply to so short-sighted a view. The exhibition comprises three main sections: (1) A series of rubber trunks affected by the chief diseases met with in the East, illustrated by admirable coloured wall-pictures of the diseases *in situ*; (2) cultures and microscopic preparations of living fungi isolated at the college from the trunks exhibited; and (3) a section devoted to the important bearing of a knowledge of the anatomy of the bark of the tree upon questions of latex yield. This section also includes trunks illustrating different systems of tapping. All the exhibits are accompanied by explanatory labels.

The principal diseases represented are as follows:

(1) *Brown Bast.*—This is by far the most important disease at the present time, and is rapidly increasing, certain estates in Java having as many as 60 per cent. of the trees attacked. It is an affection of the bark in the tapping area, and is of acute importance, since it quickly results in the complete cessation of latex flow. Later, the bark becomes discoloured and burrs appear over the affected area. The disease is met with on young and old and on vigorous and backward trees, and occurs in every type of soil. At present preventive measures are confined to disinfection and excision of the affected tissues, but successful treatment is hindered by ignorance of the real nature of the disease. Hitherto physiological disturbance produced by tapping has been held to be the cause, but recent work in Sumatra suggests a bacterial origin. Further research alone can settle this fundamental question.

(2) *Fomes lignosus.*—Next to brown bast this is the most serious disease of Hevea. It is a fungus of the familiar Polyporus type, attacking the cortex of the roots. In cases where it was neglected in the early stages it has since wiped out large blocks of rubber, and from the nature of the disease the replanting of such areas has been impracticable. The mycelium spreads to the Hevea roots from old jungle stumps, or from soil in which old jungle roots have been lying. From the infected Hevea roots it passes to all healthy roots in the vicinity, finally destroying the trees. Treatment consists in exposing the root-system and painting the diseased roots with Bordeaux mixture or other fungicide. The soil is also heavily limed to destroy the mycelium invariably present in it, and the whole infected area isolated by a trench.

(3) *Fomes pseudoferreus* (*Poria*).—This fungus penetrates deeply into the wood of the Hevea roots, often leaving the cortex as a living cylinder until the wood is destroyed by a "wet rot." The tree thus shows little external signs of attack until the disease has reached the final stage. In consequence, measures of dealing with Poria are limited to preventing its spread. The treatment adopted is essentially the same as for *Fomes lignosus.*

(4) *Dry Rot* (*Ustulina zonata*).—This fungus is a wound parasite, and gains entrance *via* lesions on roots, stems, and branches, killing the wood, which becomes soft and tindery. Owing to former neglect of wounds, the disease is greatly increasing in older plantations. The best preventive treatment is a periodical dressing of all wounds with tar. When confined to the branches the disease may be removed by pruning, but if on the base of the trunk or on the roots, the tree is usually found to be infected with Fomes in addition, and treatment is impracticable.

(5) *Patch Canker* (*Phytophthora Faberi*).—This disease is increasing in all the rubber-growing countries of the East. The bark just below the surface becomes claret-coloured, and eventually dies off in patches. The disease can be controlled by early removal of the bark and coating the exposed surface with tar, but the chief difficulty is that the affected bark is freely entered by boring beetles which penetrate deeply into the wood, carrying with them spores of dry rot (Ustulina). In consequence, nearly every case of neglected patch canker is also infected with dry rot.

(6) *Stripe Canker* (*Phytophthora sp.*).—This canker was a formidable menace during 1915–17, more than 70 per cent. of the trees in tapping on some estates being attacked. The disease first appears as narrow vertical stripes just above the newly tapped bark, and if tapping is continued during the wet season the whole of the tapping surface rots away. Fortunately, it is now almost completely preventable by daily disinfection of the tapping cut.

(7) *Pink Disease* (*Corticium salmonicolor*) has

caused much damage in the East. It rarely attacks very young trees, and develops most rapidly during periods of heavy rain. Manifestations of the disease are extremely variable, but a common form, viz. a pink encrustation on the branches or main stem, gives the disease its popular name. Once the bark is penetrated the fungus spreads rapidly, destroying the cortex, and frequently enters the wood, interrupting the water-supply to the branches, which turn brown and die. So far the best treatment has been the removal of infected branches, or by treating the diseased parts with tar. Except in special cases, spraying is not practicable.

In the section devoted to fungal cultures and preparations, the following fungi, among others, have been isolated and grown from the trunks exhibited: *Cyphella heveae*, a cause of "thread blight" disease; *Botryodiplodia theobromae*, a cause of "die-back"; *Fomes lignosus*; Hyphomycetes associated with Botryodiplodia. In addition to living cultures of these fungi on potato and banana agars, interesting experiments are in progress with the view of ascertaining the effect of the vitality of the host upon the potency of the parasite. The fungi have therefore been sown (on wounds) on apple-twigs respectively healthy, of low vitality, and dead, and the cultures kept in a saturated atmosphere and at 25° C.

The third section well illustrates by means of diagrams the important relationship between the anatomy of the rubber stem and the yield of latex. In high-yielding trees the bark shows a large number of rings of latex tubes and a high relative proportion of soft bast as compared with hard bast, which latter contains abundant groups of stone-cells interrupting the rings of latex tubes. In good yielders the stone-cells are more or less confined to the external part of the cortex; in low yielders they are distributed in depth. The well-known superior yield of tapping cuts made from left to right over cuts made from right to left is due to the oblique course of the latex tubes in the bark. This important fact is explained in a large diagram. Mr. H. Ashplant exhibits elaborate statistics showing individual daily tapping yields obtained by different coolies on one estate over a period of three years. The figures show that highly skilled tappers working a group of trees previously tapped by average or poor tappers may collect from 50 to 200 per cent. more latex than the unskilled men. This fact results from the variable depth of the cut made by the inferior tappers, who do not reach the more internal rings of latex tubes. A further interesting point is the favourable influence of a good tapper's work on the yield obtained by an average tapper succeeding him in the same block.

It is much to be hoped that efforts will be made to maintain and develop the present exhibition as a permanent museum of the economic mycology of *Hevea brasiliensis*. Such a museum, with its natural complement of an information bureau, would be of the greatest practical value to the home representatives of planting interests and to the industry generally. The exhibition demonstrates in the clearest fashion the supreme importance of scientific research in this vital aspect of rubber-planting. New diseases are bound to occur in the future, and it may be disastrous to wait until the plantations are seriously affected before taking steps to secure expert advice. Adequate scientific staffs should be continuously engaged in studying the complete biology of Hevea, so that in the advent of a new disease experienced specialists could be detailed at once to cope with it. It is, however, essential that such staffs should be composed of men of first-rate ability and training, for where so much is at stake anything short of the best is worse than useless. Moreover, the best men afford the greatest chance of effecting the desideratum in combating all disease, viz. the stitch in time. The industry must be prepared to pay for such men, but there can be no question that money generously and wisely spent on these lines would be repaid times over.

The Position of the Meteorological Office.

DR. C. G. KNOTT, president of the Scottish Meteorological Society, has sent us a copy of the following resolution passed by the council of the society with reference to the present position of the Meteorological Office:—

"The council of the Scottish Meteorological Society have had under consideration the information published regarding the future status of the Meteorological Office and its relation to various Departments of State. They recognise that an incorporation in one of the great Departments of State is desirable, and realise that meteorology has much to gain by an intimate connection with the Air Ministry. At the same time they have in view that the State Meteorological Office has many other departments and interests to serve, not the least of which are those of pure research. They feel that any system by which the policy of the Office was directed by the interests of only one Department might in certain circumstances hamper its proper development. The science of meteorology made notable advances in many directions under the liberty enjoyed by the Director of the Office with the administrative committee as constituted in 1905. The council urge that, whatever constitution it may be convenient to give to the Office, the public, departmental, and scientific interests of the science should be safeguarded by expressly and personally charging the Director with the care of meteorology in all its branches. Under such an instruction the Director could be relied upon to organise the service upon a scientific plan and to build up the administrative elements in accordance with the demands made upon him. The council also feel that any step which will modify the functions and responsibilities of the Meteorological Committee should be taken only after searching inquiry by a Departmental Committee into the necessity for any modification, and the probable effect of such modification on the work of the Meteorological Committee."

Earthworks and Retaining Walls.

IT is admitted that our knowledge of earthwork problems is far from complete, and the information given in two papers read at the Institution of Civil Engineers on February 10 forms a welcome addition. Mr. Ponsonby Moore Crosthwaite has made experiments on the horizontal pressure of sand, and finds that the angle of internal friction is much less than the angle of repose. The experiments show that the pressures on a wall, as calculated from the Rankine and Colomb theories, are much too high, especially for surcharged walls. Further experiments show that the wedge theories which take account of the friction between the wall and its backing give correct results if the wall is not surcharged, but break down for surcharged walls. By modifying the wedge theory so as to neglect the friction on the back of the wall, and introducing the angle of internal friction instead of the angle of repose, marked agreement was found with the experiments for surcharged walls.

Experiments were made with the object of testing whether the friction between the wall and the backing was of importance, and these showed that this friction did not affect the horizontal thrust.

The second paper, by Mr. Angus Robertson Fulton, gives an account of experiments made on the overturning moments on retaining walls. The method of direct measurement of the moment was employed; the filling was of three kinds: (1) clean river sand, (2) gravel, and (3) garden soil. The total height without surcharge was limited to 7 ft., and with surcharge it reached 9 ft. The experiments without surcharge show that results calculated from the Rankine theory are greatly in excess of the observed values, while those obtained from the wedge theory approximate fairly closely to experiment. For surcharged vertical walls with unlimited slope the wedge and Rankine formulæ give values too great by 20 and 50 per cent. respectively. In the whole series of experiments the greatest discrepancy occurred with the 7-ft. levels (no surcharge) when gravel-filling was used, and was worst with the wall inclined outward. Low experimental values were also obtained in the sand tests at the lower level under surcharge. Mr. Fulton concludes that the wedge theory gives good results with material uncompacted for walls in which the inclination of the inner face is not greater than usually obtains in practice.

Fellowship of the New Zealand Institute.

AT the annual meeting in 1919 of the Board of Governors of the New Zealand Institute it was decided to establish a fellowship of the institute, since —apart from Hutton and Hector memorial medals, which can be gained only by very few—there are no honours attainable in the Dominion for those engaged in scientific research, the number of whom has greatly increased in recent years, while more branches of science are pursued than formerly. This fellowship, which entitles the recipient to place the letters "F.N.Z.Inst." after his name, is limited to forty fellows, and not more than four are henceforth to be elected in any one year until the number is complete, after which only such vacancies as occur may be filled.

In order to make a commencement, and as there were many who well deserved recognition for their long and valuable services to science, it was resolved that, in the first place, twenty original fellows should be appointed, these to consist of the living past-presidents, together with Hutton and Hector medallists (ten in all), and of ten more members of the institute who were to be elected by the past-presidents and medallists from persons nominated by the various affiliated branches of the institute.

The fellowship is to be given only for research or distinction in science, and it is plain that the distinction even now is far from easy of attainment, and that, as time goes on, its value will greatly increase. The election and appointment of the original fellows took place at the close of 1919, and resulted as follows:—Mr. B. C. Aston, *‡Prof. W. B. Benham, †Mr. Elsdon Best, *†Mr. T. F. Cheeseman, *†Prof. Chas. Chilton, *†‡Dr. L. Cockayne, †Prof. T. H. Easterfield, Prof. C. C. Farr, Mr. G. Hogben, Mr. G. V. Hudson, Prof. H. B. Kirk, †‡Dr. P. Marshall, *Dr. D. Petrie, †Sir Ernest Rutherford, Prof. H. W. Segar, Mr. S. Percy Smith, Mr. R. Speight, Prof. A. P. W. Thomas, *the Hon. G. M. Thomson, and Dr. J. Allan Thomson. * signifies past-president; † Hector medallist; and ‡ Hutton medallist.

The Proposed University of Reading.

LORD HALDANE'S conception of the division of the country into areas in each of which a "civic university" caps the provincial education scheme is coming to be recognised as not only wise and far-seeing, but also essential. In Georgian and Victorian days a university was looked upon as primarily an institution for the completion of the teaching work of public schools. The wider view is taken now of the university as a focus of the intellectual life of the community which it serves and as a centre for research.

When in 1902 it was proposed that the Victoria University should be split up into the Universities of Manchester and Liverpool, many regarded the multiplication of degree-giving bodies with apprehension. It was feared that it would lead to a competition downwards. The reverse of this has happened. Leeds, Sheffield, and Bristol have secured independent universities, and each of them fears, above all things, the imputation that its degrees are less desirable than those of any other.

Reading is now seeking a charter. This project is not new. In 1911 the college received great endowments from Mr. and Mrs. G. W. Palmer, Lady Wantage, and Mr. Alfred Palmer, given for the purpose of enabling it to qualify for a charter. The scheme was interrupted by the war, but has now been taken up again with the utmost vigour. Three or four only of our modern universities have so large a permanent source of income. Its students are now more numerous than were those of two chartered English universities before the war.

In the provision of residential accommodation Reading is unique. Its six hostels lodge upwards of four hundred students. The college has also certain definite claims to be regarded as a national institution. In addition to the faculties of letters and science and the departments of fine arts, music, and domestic subjects, its distinctive line of study is agriculture, horticulture, and dairying. In these subjects it is a most important centre of research. Students go to it, not only from the whole of the United Kingdom, but also from the Continent and the British Dominions overseas.

The desire for independence is most natural. As matters stand at present, its professors and lecturers have no voice in determining the conditions for degrees, in settling the syllabuses of teaching, in carrying out the examinations, or in marking their students' answer-papers.

University and Educational Intelligence.

CAMBRIDGE.—Prof. Horace Lamb, Sir Thomas L. Heath, Prof. W. H. Bragg, and Dr. Henry Head have been elected honorary fellows of Trinity College.

Mr. A. Amos, Downing College, has been appointed University lecturer in agriculture, and Mr. G. U. Yule, St. John's College, re-appointed University lecturer in statistics.

A Smith's prize has been awarded to S. Pollard, fellow of Trinity College, for an essay on "The Stieltjes Integral and its Generalisations."

The following grants have been made from the Gordon-Wigan fund:—50*l.* for plant-breeding experiments, 50*l.* for an experimental gas chamber in the physiological laboratory, 50*l.* to assist in the provision and display of entomological specimens, 30*l.* to help in the study of Pleistocene deposits round Cambridge, and 50*l.* towards a deficit on the working of the botanical department.

The Secretary of the Royal Commission on Oxford and Cambridge Universities gives notice that all members of the University who desire to submit representations on matters falling within the terms of reference of the Commission should forward written memoranda in triplicate to him at 22 Carlisle Place, S.W.1, if possible by the middle of April.

Fresh regulations for the diplomas in agriculture and forestry have been drafted. It is proposed to establish a diploma in horticulture, and, further, to include horticulture in the subjects to be examined upon for the degree of B.A. in agriculture, estate management, and forestry.

THE Senate of the University of Dublin has decided to grant the following honorary degrees:—*D.Litt.*: Dr. William Crooke. *LL.D.*: Lord Bryce and Sir Donald MacAlister. *M.D.*: Sir Archibald E. Garrod, Regius professor of medicine in the University of Oxford. *D.Sc.*: Prof. W. H. Bragg, Quain professor of physics in the University of London, and Prof. R. A. Millikan, professor of physics in the University of Chicago.

A ROYAL COMMISSION has been appointed to inquire into the financial resources and working of the University of Dublin and of Trinity College, Dublin, and to consider the application which has been made by the University for State financial help. The members of the Commission are:—Sir Archibald Geikie, Sir John Ross, Dr. A. E. Shipley, Prof. J. S. E. Townsend, and Prof. J. Joly. Prof. G. Waterhouse is to be the secretary to the Commission.

THE governing body of the Imperial College of Science and Technology has made arrangements for the provision, partly from its own funds and partly from the gifts of donors for this special purpose, of six post-graduate scholarships for advanced work and research to be held in the coming year at American universities. It is hoped that arrangements may be made for interchange by the reception at the Imperial College of a corresponding number of university students from America. Lord Crewe, chairman of the governing body, has received the following letter from Viscount Grey:—"It is most desirable that young men of the rising generation, who will do much of the public work here and in America in the coming years, should get to know each other's universities. It will help both countries to realise how much the British and American peoples have in common, not merely in language, but in thought and in political views and aspirations. I am sure the interchange of students between British and American universities is most valuable both to individual students themselves and generally in promoting friendship based upon true understanding."

A WELL-ATTENDED meeting of teachers of the Incorporated Colleges and Schools of the University of London was held at King's College on Friday, March 12, under the chairmanship of Prof. W. A. Bone, of the Imperial College of Science and Technology, to consider the position of university teachers in relation to the Teachers (Superannuation) Act. The chairman pointed out that, as the Act is framed, university teachers are expressly excluded from its benefits. This exclusion will inevitably set up a barrier between the schools and the universities, and prevent the free transition of teachers from the one to the other, especially as the salaries of university lecturers compare most unfavourably with those in the better secondary schools. Financially, the benefits under the Teachers Act are much greater in almost all respects than under the existing contributory scheme for university teachers, which makes no provision in respect of the years of service of a teacher prior to his joining the scheme, whereas the Act is retrospective and takes account of all years of recognised service. As the scheme was only instituted in 1913 this is a matter of serious concern to the older university teachers, for whom the provision on retirement is totally inadequate. The new scales of salaries and the Teachers Superannuation Act have made the school-teaching profession much more attractive than in the past, and unless the universities are placed in a position to offer salaries and retiring allowances at least comparable with those offered to teachers in secondary schools, they cannot maintain their efficiency and attract the abler graduates to their service. After discussion the following resolution was passed with only five dissentients:—"That this meeting of whole-time teachers in the Incorporated Colleges and Schools of the University of London hereby requests the Government to extend to university teachers and administrative officers all the benefits of the School Teachers (Superannuation) Act, 1918." A committee was appointed to take further action in conjunction with the Association of University Teachers.

Societies and Academies.

LONDON.

Royal Society, March 4.—Sir J. J. Thomson, president, in the chair.—Dr. F. F. **Blackman**: The protoplasmic factor in photo-synthesis. The centre of interest in problems of the photo-reduction of CO_2 in green photo-synthesising cells is shifting from the chlorophyll to the protoplasm. The quantitative control of photo-synthesis in the normal green cell is determined protoplasmically. This is illustrated by the temperature relations, which are not those of a photo-chemical reaction, but of a dark reaction. The photo-synthetic activities of leaves of different varieties (green *v.* golden leaves) and at different stages of development show no relation to the amount of chlorophyll that they contain, as is brought out by the "assimilation numbers" of Willstätter. The relation between chlorophyll development and photo-synthesis development, described in the next communication, furnishes another instance of the dominance of factors other than the pigment. In many lower organisms we find the power of reducing CO_2 to form organic matter by chemical energy in the absence of pigment or light. This chemo-synthesis may be the sole or only an alternative source of the carbon for the living cell. The process involves, of course, no cosmic gain of energy. In these cases the efficiency of energy transference from the oxidation of various substances to the reduction of CO_2 seems to be as great as or greater than in the utilisation of light energy for photo-reduction of CO_2.—G. E. **Briggs**: The beginning of photo-synthesis in the green leaf. In young leaves development of the power of photo-synthesis is found to lag behind development of chlorophyll, so that a green leaf when young may exhibit very slight or zero photo-synthetic power. This means that photo-synthetic activity demands development of some other internal factor than chlorophyll. The potentiality of this other factor rapidly increases with age day by day, even when the leaf is kept in darkness continuously. By keeping a leaf in a very low partial pressure of oxygen, further development of chlorophyll can be completely arrested, even in continuous light. Here also, starting with a leaf of feeble green tint, there is similar day-by-day increase in photo-synthetic power, in spite of there being no further greening. Experiments were carried out by

means of a new apparatus designed by Dr. F. F. Blackman for measuring a small output of oxygen in photo-synthesis. The leaf is illuminated in a closed circuit in an atmosphere of hydrogen and carbon dioxide. In part of the circuit gases are carried over palladium black, so that oxygen produced unites with two volumes of hydrogen. The threefold reduction of volume resulting is measured by a gas burette in the circuit. In this apparatus oxygen pressure is kept so low that no further development of chlorophyll takes place, while photosynthetic production of oxygen can be measured with great accuracy. If a leaf is cut from a seedling growing in the dark at an early stage of development, and then partially greened by exposure to light in air, its photo-synthetic activity when transferred to the apparatus will be very small or nothing. If exactly the same procedure is repeated a few days later, the photo-synthetic activity may be nearly as great as in the normally developed leaf.—Dr. B. **Moore**, E. **Whitley**, and T. A. **Webster**: Sunlight and the life of the sea. [Studies of the photo-synthesis in marine algæ. (1) Fixation of carbon and nitrogen from inorganic sources in sea-water; (2) increase of alkalinity of sea-water as a result of photo-synthesis and as a measure of that process; and (3) relative photo-synthetic activity of green, brown, and red seaweeds in light of varying intensity.] The vernal outburst of green life which occurs at the spring equinox is occasioned by the rapid change in intensity of daily illumination. A study of the seasonal variations in plankton around Port Erin, Isle of Man, has now been carried on for many years by Prof. W. A. Herdman and his co-workers. In many years the great outburst of diatoms occurs before the temperature of the water has even begun to move from its winter level. It thus becomes clear that it is the longer, brighter day, with increased altitude of the sun, which is the primary factor in the sudden dawn of the life of the sea each spring. This is illustrated by a chart upon which are shown for each month (1) temperature of the sea, (2) number of diatoms, (3) hours of bright sunshine, (4) total radiant energy, and (5) the amounts of nitrogen peroxide present in the air (formerly called "ozone of the air" or "active oxygen"), as taken at Radcliffe Observatory, Oxford, by Schönbein's "Ozone" papers. A sudden rise in radiant energy in March is accompanied by (1) the diatomic outburst and (2) increased nitrite content. It has been shown that the growing diatoms capture this enormous increase of light, and utilise it for building both carbon and nitrogen into their organic substances. The source of the nitrogen is the atmospheric elemental nitrogen dissolved in the sea-water, and not ammonia, nitrites, or nitrates. The source of the carbon is the carbon dioxide of the bicarbonates of calcium and magnesium dissolved in sea-water. As this carbon is removed in photo-synthesis the sea becomes always more alkaline, and the change of reaction can be used as a rough measure of the marine crop. Although the increase of alkalinity is small, yet the volume of sea-water is so immense that, as has been pointed out by Moore, Prideaux, and George Herdman, supposing this to happen to a depth of 100 metres over the surface of the sea, then the crop of moist plankton per square kilometre would amount to about 1,500,000 kilograms. This corresponds roughly to about 10 tons per acre.

Royal Microscopical Society, February 18.—Prof. John Eyre, president, in the chair.—Dr. Agnes **Arber**: (1) Studies on the binucleate phase in the plant-cell. Rudolf **Beer** and Dr. Agnes **Arber**: (2) Multinucleate cells: an historical study (1879–1919). These two papers were read as one. It was pointed out that in 1844 Nägeli first stated that the plant-cell is essentially uninucleate. Those botanists who have from time to time directed attention to exceptions to Nägeli's rule, usually attributed little importance to them, but recent work has made it clear that a binucleate or multinucleate condition is a very constant character of young and active tissues. The authors' observations on the subject were then discussed, the case of the nuclei of the young inflorescence axis of *Eremurus himalaicus* being described in detail. It was shown that the binucleate condition arises by mitosis. The division is normal up to the formation of the daughter-nuclei and the initiation of the cell-plate. At this point the mechanism apparently breaks down, the cell-plate is resorbed, and the spindle-fibres and associated cytoplasm—the "phragmoplast" of Errera —become transformed into a hollow sphere which encloses the two daughter-nuclei, and eventually, by gradual expansion, merges with the cytoplasm lining the cell-wall. For this hollow shell, derived from the phragmoplast, the authors have proposed the term "phragmosphere" (Proc. Roy. Soc., B, vol. xci., 1919, p. 10). The question as to how the binucleate condition of these young cells passes into the uninucleate condition characteristic of mature tissues, was then considered. It was shown that, although bilobed nuclei often occur, which at first sight suggest that the two nuclei have fused together, more critical examination indicates that these nuclei are *single nuclei*, the lobing of which is an indication either of senility (axis of Asparagus) or, in some cases, of an effort by young and active cells to increase their nuclear surface (stelar parenchyma of roots of Stratiotes, leaf epidermis of Hemerocallis). The authors think it more probable that the uninucleate condition is restored by degeneration and resorption of one nucleus, than by the fusion of the two nuclei. The paper closed with a brief reference to the significance of the multinucleate phase.

MANCHESTER.

Literary and Philosophical Society, February 3.—Sir Henry A. Miers, president, in the chair.—Prof. E. **Knecht**: Alpine insolation effects on unprotected wood. Effect of direct sunshine on the wood of Alpine chalets. When exposed for about a hundred years the surface of the wood was sometimes charred or scorched to a uniform black, presenting under the microscope the appearance of coal. The changes were probably brought about more by thermo-chemical than by photo-chemical action. By prolonged heating of wood to 93° C. the author had produced incipient blackening of the surface. The temperature of decomposition of wood appeared to have an important bearing on the question of coal-formation.—W. **Thomson** and H. S. **Newman**: The behaviour of amalgamated aluminium and aluminium wire. Investigations on the fine feathery growths produced when aluminium wire is brought into contact with mercury. No such growths are obtained from amalgamated magnesium, although it undergoes oxidation more readily than aluminium at the ordinary temperatures of the air.—C. E. **Stromeyer**: The after-effects of cannibalism. Cannibalism would not be indulged in by people with vegetarian tastes, or by those who, having a craving for animal food, could satisfy it. Others who had this craving, but no animals to eat, would become cannibals. No State in which indiscriminate man-eating was indulged in could have flourished. Officials were therefore appointed who invented rites which became religious ceremonies. Human sacrifices were, to a certain extent, discontinued, but the rites were con-

tinued. Religious animal sacrifices of the ancients were an after-effect of human sacrifices; as is possibly our practice of saying grace before meat.

PARIS.

Academy of Sciences, February 23.—M. Henri Deslandres in the chair.—M. L. **Mangin** gave an account of the life-work of Emile Boudier, correspondant in botany.—H. **Andoyer**: The method of Gauss for the calculation of secular perturbations.—L. **Maquenne** and E. **Demoussy**: The absorption of calcium by plant-roots and its antitoxic properties towards copper. Calcium does not prevent the absorption of copper by the roots of plants, and copper does not prevent the assimilation of calcium. The antitoxic action of calcium, experimental proofs of which are given, is of a physiological order; it prevents a dangerous accumulation of the poisonous metal.—Y. **Delage**: Suggestion for the reason for the double fovea of certain birds of prey.—W. **Kilian**: The repartition of the facies of the Palæo-Cretaceous in the structural units of the south-east of France.—J. **Hadamard**: Report on the works examined and retained by the Ballistics Committee during the period of the war.—Prof. Michelson was elected a foreign associate in succession to the late Lord Rayleigh, and M. Camille Viguier a correspondant for the section of anatomy and zoology in succession to the late Gustaf Retzius.—N. **Sakellariou**: The oblique linear and surface curvature of a surface.—H. **Villat**: Certain cyclic movements with or without vortices.—C. **Rabut**: Light concrete: the calculation of increase of power resulting from its use in building. Slag concrete is lighter than concrete made up with sand or gravel. A sketch of the theory of its application is given.—P. **Le Rolland**: The influence of the deformation of the knife-edge and of the plane of suspension on the time of swing of a pendulum.—H. **Georges**: A new alternating mercury arc. A description of a new quartz mercury lamp which with electromotive forces of more than 500 volts starts cold.—L. **Guillet**: The alloys of copper, zinc, and nickel. An account of the mechanical properties of alloys containing copper, 46 and 40·5 per cent.; zinc, 43·2 and 44·7 per cent.; and nickel, 10·4 and 14·4 per cent. Comparisons with brasses free from nickel are added. Compared with brass, these alloys possess advantages in colour, greater resistance to oxidation, and facility of forging at high temperatures.—C. **Matignon** and M. **Fréjacques**: The dissociation of ammonium carbamate. Dissociation pressures are given for temperatures ranging from 100° to 150° C.—M. **Tiffeneau** and A. **Orekhoff**: The transposition of the phenyl group in the tetrahydronaphthalene series.—R. **Souèges**: The embryogeny of the Chenopodiaceæ. Development of the embryo in *Chenopodium Bonus-Henricus*.—L. **Emberger**: The evolution of the chondriome in the formation of the sporangium in ferns.—J. **Pottier**: The generality of the foliar asymmetry in mosses.—P. **Dangeard**: The evolution of the vacuolar system in Gymnosperms.—P. **Portier** and Mme. Lucie **Randoin**: The creation of vitamines in the intestines of rabbits receiving nourishment sterilised at a high temperature.

DIARY OF SOCIETIES.

THURSDAY, MARCH 18.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Stephen Graham: The Spirit of America after the War.

ROYAL SOCIETY, at 4.30.—W. B. Brierley: A Form of *Botrytis cinerea* with Colourless Sclerotia.—R. R. Gates: A Preliminary Account of the Meiotic Phenomena in the Pollen Mother Cells and Tapetum of Lettuce (*Lactuca sativa*).

LINNEAN SOCIETY, at 5.—Dr. J. Small: The Chemical Reversal of Geotropic Response in Roots and Stems.

ROYAL COLLEGE OF PHYSICIANS, at 5.—Sir John R. Bradford: The Clinical Experiences of a Physician during the Campaign in France and Flanders, 1914-1919 (Lumleian Lecture).

ROYAL INSTITUTE OF PUBLIC HEALTH, at 5.—Dr. S. V. Pearson: Suggested Reforms in the Campaign against Tuberculosis.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—W. R. Jones: Tin and Tungsten Deposits: The Economic Significance of their Relative Temperatures of Formation.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Adjourned Discussion on the Papers of W. H. Patchell and S. H. Fowles read at the Meeting on March 11.

CHEMICAL SOCIETY, at 8.—I. Masson and R. McCall: The Viscosity of Nitrocellulose in Mixtures of Acetone and Water.—H. Stephen, W. F. Short, and G. Gladding: The Introduction of the Chloromethyl Group into the Aromatic Nucleus.—H. E. Cox: The Influence of the Solvent on the Velocity of Reaction between certain Alkyl Iodides and Sodium β-Naphthoxide.—H. Crompton and P. L. Vanderstichele: The Use of 1:2-Dichlorovinylethyl Ether for the Production of Chloroacetates and Acid Chlorides.

SOCIETY OF ANTIQUARIES, at 8.30.

FRIDAY, MARCH 19.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir William S. Meyer: The Indian Currency System and its Developments.

CONCRETE INSTITUTE, at 6.—Dr. O. Faber: The Practical Application of Reinforced Concrete.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—D. Brownlie: Exact Data on the Performance of Mechanical Stokers, as applied to "Lancashire" and other Narrow-flued Boilers.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—W. H. F. Robba: Shipbuilding and Shipping Developments in Italy.
ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Dr. A. E. Barclay and Others: Discussion on Radium-Therapy and Radio-Therapy of Exophthalmic Goitre.—Dr. S. Russ: Vision by Ultra-violet Light.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—E. McCurdy: Leonardo da Vinci.

SATURDAY, MARCH 20.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir J. J. Thomson: Positive Rays.
PHYSIOLOGICAL SOCIETY (at University College), at 4.—J. F. Donegan and Others: Innervation of Veins.

MONDAY, MARCH 22.

ARISTOTELIAN SOCIETY (at 74 Grosvenor Street, W.1), at 8.—C. C. J. Webb: Obligation, Autonomy, and the Common Good.
MEDICAL SOCIETY OF LONDON, at 8.30.—E. M. Little and Others: Discussion on the Re-education of the Amputated.
ROYAL GEOGRAPHICAL SOCIETY (at Philharmonic Hall), at 8.30.—Sir Ernest Shackleton: The 1914-1917 Antarctic Expedition.

TUESDAY, MARCH 23.

ROYAL ANTHROPOLOGICAL INSTITUTE AND PREHISTORIC SOCIETY OF EAST ANGLIA (Joint Meetings) (at Geological Society), at 3.—The Prehistoric Society of East Anglia.—Prof. J. E. Marr: Man and the Glacial Period (Presidential Address).—H. Dewey: Flat-based Celts from Kent, Hampshire, and Dorset.—Dr. A. E. Peake: Exhibit of Specimens found at Grime's Graves in 1919.
ROYAL HORTICULTURAL SOCIETY, at 3.—Rev. J. Jacob: Wandering down Old Garden By-roads.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. Keith: British Ethnology—The Invaders of England.
ROYAL COLLEGE OF PHYSICIANS, at 5.—Sir John R. Bradford: The Clinical Experiences of a Physician during the Campaign in France and Flanders, 1914-1919 (Lumleian Lecture).
INSTITUTION OF CIVIL ENGINEERS, at 5.30.—Col. D. Lyell: The Work done by Railway Troops in France during 1914-1919.
ROYAL ANTHROPOLOGICAL INSTITUTE AND PREHISTORIC SOCIETY OF EAST ANGLIA (Joint Meetings) (at Geological Society), at 6.—Prof. A. Keith: How Far Cranial Characters can Help in Estimating the Antiquity of Human Remains. (Lantern.)
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Technical Meeting), at 7.—Dr. B. Glover: Factorial and Time Methods of Development applied to Bromide and Gaslight Papers: Theoretical Principles and Practical Demonstrations.
FARADAY SOCIETY (at Chemical Society), at 7.30.—General Discussion:—Basic Slags: Their Production and Utilisation in Agricultural and other Industries. Prof. F. G. Donnan will preside over the discussion.—Dr. E. J. Russell will open the discussion and give a general survey of the subject.—Prof. C. H. Desch will discuss the subject from the Physico-Chemical Standpoint.—Sir T. H. Middleton: The National Aspects of the Case for Increasing the Supplies of Basic Slag.—Sir A. Daniel Hall: The Demand for Basic Slag.—Prof. D. A. Gilchrist: Basic Slag and its Place in the Development of Agriculture.—G. Scott Robertson: A Comparison of the Effect of various Types of Open-hearth Basic Slag on Grassland.—Dr. J. E. Stead, F. Bainbridge, and E. W. Jackson: Papers on Solubility of Basic Slags.—D. Sillars: The Formation of Basic Slag in the Manufacture of Steel.—W. S. Jones: The Improvement of Low-grade Basic Slag.

WEDNESDAY, MARCH 24.

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 11.—The Earl of Durham: Presidential Address.—Sir Eustace D'Eyncourt: H.M.S. *Hood*.—A. W. Johns: German Submarines.—G. S. Baker: Model Experiments in Connection with Submarine Warfare.
ASSOCIATION OF ECONOMIC BIOLOGISTS (General Meeting) (in Botany School of the Imperial College of Science and Technology), at 11.30.—Short Communications and Exhibitions.—D. W. Cutler: The Relation of Protozoa to Soil Problems.—Winifred E. Brenchley: Correlation between Seed and Crop.—At 2.15.—Dr. W. Lawrence Balls: The Nature and Scope of Botanical Research in the Cotton Industry.—M. C. Rayner: The Calcifuge Habit in Ling (*Ca luna vulgaris*) and other Ericaceous Plants.—H. Wormald: Shoot Wilt of Plum Trees.
ROYAL SOCIETY OF ARTS, at 4.30.—L. Gaster: Industrial Lighting in its relation to Efficiency.
GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Mrs. E. M. Reid: Two Pre-Glacial Floras from Castle Eden, Durham, and a Comparative Review of Pliocene Floras, based on the Study of Fossil Seeds.
PSYCHOLOGICAL SOCIETY (Industrial Section) (at Examination Rooms of the Royal College of Physicians, 8-11 Queen Square, W.C.1), at 6.—Miss G. Broughton: The Psychological Causes of the Wastage of Labour in Factories employing Women.

THURSDAY, MARCH 25.

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 11.—Sir Alfred Yarrow: Notes on our Economic Position as a Shipbuilding Country.—J. Anderson: Further Notes on the Dimensions of Cargo Steamers.—Dr. J. Bruhn: Freeboard and Strength of Ships.
INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 3.—P. R. Jackson: The Stabilisation of Ships by means of Gyroscopes.—Prof. K. Suyehiro: Yawing of Ships caused by Oscillation amongst Waves.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Stephen Graham: The Hope for Russia.
ROYAL SOCIETY, at 4.30.—*Probable Papers*: Prof. A. R. Forsyth: Note on the Central Differential Equation in the Relativity Theory of Gravitation.—R. D. Oldham: The Frequency of Earthquakes in Italy in the Years 1896 to 1914.—A. F. Dufton: A New Apparatus for Drawing Conic Curves.—Capt. J. W. Bispham: An Experimental Determination of the Distribution of the Partial Correlation Coefficient in Samples of 30.
CHEMICAL SOCIETY (Annual General Meeting), at 5.—Sir James J. Dobbie: Presidential Address.
ROYAL COLLEGE OF PHYSICIANS, at 5.—Sir John R. Bradford: The Clinical Experiences of a Physician during the Campaign in France and Flanders, 1914-1919 (Lumleian Lecture).
CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. E. Sloan Chesser: Adolescence and the Continuation Schools.
INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Discussion on:—(*a*) The Electrical Equipment of Artisan Dwellings (with Introductory Paper by L. Milne). (*b*) The Report of the Wiring Sub-Committee of the Wiring Rules Committee of the Institution.
INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 7.30.—C. I. R. Campbell and C. H. May: The Effect of Size upon Performance of Rigid Airships.—Prof. E. G. Coker and A. L. Kemball, jun.: The Effects of Holes, Cracks, and other Discontinuities in Ships' Plating.
CHEMICAL SOCIETY (Informal Meeting), at 8.

FRIDAY, MARCH 26.

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 11.—Eng.-Com. H. B. Tostevin: Experience and Practice in Mechanical Reduction Gears in Warships.—J. J. King-Salter: The Balancing of Rotors and Determining the Position and Amount of the Balancing Weights.—Prof. T. H. Havelock: Turbulent Fluid Motion and Skin Friction.
PHYSICAL SOCIETY OF LONDON, at 5.—Prof. A. S. Eddington and Others: Discussion on Einstein's Theory of Relativity.
WIRELESS SOCIETY OF LONDON (at Institution of Civil Engineers), at 6.—Capt. L. A. T. Braidwood: Harmonics in Continuous Wave Transmissions (Illustrated by Lantern Slides and Experiments).
INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—P. L. Young and Others: Discussion on Foundry Memories.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir J. J. Thomson: The Scientific Work of the late The Right Hon. Lord Rayleigh.

SATURDAY, MARCH 27.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir J. J. Thomson: Positive Rays.

TO-DAY, in almost every sphere of activity, as is widely recognised, the majority of the important problems that have to be handled are largely technical in character; this is so whether these problems lie in the broad domain of national policy, in the narrower limits of administrative action, or in the restricted fields of executive performance. To this situation is due, as is well known, the need that has arisen in recent times for that high degree of specialisation in certain kinds of knowledge which has revolutionised the scheme of organisation of the *personnel* in the fields of commerce and industry, and is likewise responsible for the introduction, in many enterprises throughout the world, of the *régime* of the expert.

Being, comparatively speaking, a newcomer in the realms of officialdom, the modern technical expert has still to be assigned his place of precedence there, and at the same time to have the scope of his authority and the dignity of his status definitely determined and unequivocably declared. These are matters calling for early attention, for a suspicion exists, not without foundation, that, whilst in commercial and industrial circles the expert has been very generally permitted to occupy a position of influence compatible with the importance of his *métier*, in the governmental sphere the expert has, more often than not, been relegated to a position in which his every purpose is rendered more or less ineffectual, one, moreover, in which the exercise of his legitimate activities is barely tolerated by those occupying the clerical or controlling positions.

During the past few years the prevailing uneasiness regarding the unsatisfactory footing on which the technical staff in the public services finds itself has been quickened, owing largely to an appreciation on the part of the public of the fact that it was the failure in governmental quarters to give heed to the advice of the technical expert that was responsible for bringing the country to the brink of a dire catastrophe—one, indeed, which, at the crisis of the late war, threatened its continued existence as an independent people, one from which it escaped with but a very narrow margin.

The British public had been persuaded to believe that any deficiency in the military establishments of the country was more than counterbalanced and compensated for by reason of the high perfection to which every detail connected with the Royal Navy had been brought. In the circumstances, the public may well be pardoned for the belief so firmly held by it before the Great War that the British Navy had nothing whatever to learn from either friend or foe.

That the popular conceptions on the foregoing matters were in many respects erroneous now stands out in cold print in the pages of Lord Jellicoe's "The Grand Fleet, 1914–16."[1] In the preface to this book it is stated in unequivocal terms that the Germans were "superior to us in material." The gallant Admiral does not limit himself to generalisations, but on many a page he particularises the specific matters in which the equipment or arrangements on our battleships were deficient, defective, or obsolete, and our defence works wanting. For example, he states: "The Jutland battle convinced us that our armour-piercing shell was inferior in its penetrative power to that used by the Germans." "Some delay occurred in improving our range-finders. . . . Our most modern ships were provided with range-finders 15 ft. in length, but the majority of the ships were fitted with instruments only 9 ft. long. During 1917 successful steps were taken to supply range-finders up to 25 ft. and 30 ft. in length; a series of experiments with stereoscopic range-finders was also instituted in the same year. It had become known that the Germans used this type of range-finders." "The use of smoke screens was closely investigated as a result of our experience of the German use of this device." "Neither our searchlights nor their control arrangements were at this time of the best type." The foregoing are but a few of the specific matters in which the foremost Navy in the world is recorded to have been outstripped, at a critical period of the war, by a rival of new creation.

In other directions, too, was Great Britain lacking in the matter of naval defence. For example, reference is made by Lord Jellicoe to the fact that harbour defences and obstructions were non-existent in the early days of the war. Again, it is stated that in the matter of gunnery and torpedo practices considerable leeway had to be made good. As regards the former, after the outbreak of war a great extension of the system of director firing, by which one officer or man can

[1] Published by Cassell and Co., Ltd. Price 31s. 6d. net.

lay and fire all the guns of a ship, was made (in August, 1914, only eight battleships had been fitted with this system).

In the face of the disclosures made in connection with the Battle of Jutland, it may well be asked whether the deficiencies and defects to which attention has been directed could have been foreseen in peace time and provided against. Little doubt on the subject can be left in the minds of those who read in a spirit of inquiry "Fifty Years in the Royal Navy," the autobiography of Admiral Sir Percy Scott[2]; the matters dealt with therein provide a direct answer to the foregoing question. In many of the pages of this autobiography will be found the story of the striving, over a long period of years, after progress and efficiency in relation to various details connected with the Senior Service, and of the obstinate opposition to all reforms which was constantly met with by those who were in pursuit of essential improvements. The remarks of Sir Percy Scott on every subject the theme of which relates to the attempt to introduce into the public service some new idea or device, or some improvement on existing apparatus, machinery, or methods, have all the same ring about them. In relation to every one of the matters to which the distinguished Admiral refers, the conduct of those in the controlling positions was consistent; in every instance the advice and assistance of the expert were ignored, either until it was altogether too late, or until considerable harm had been done and the waste of much public money, if not also the loss of valuable lives, involved.

Sir Percy Scott tells us that it was so long ago as February 10, 1909, that battle practice first took place, at Tetuan, with extemporised director firing. Yet it took the Admiralty two years to come to a decision as to its introduction into the Navy, and the Board waited for eight years—indeed, until the nation had for nearly three years been involved in a life-and-death struggle—before it adopted the system generally.

Another remarkable illustration of Admiralty methods mentioned by Sir Percy Scott is that connected with the depth charge, which ultimately turned out to be the antidote to the submarine. The design of a depth charge, actuated by a hydrostatic valve, was submitted by Capt. P. H. Colomb on October 1, 1914. The idea was so simple that these depth charges could have been supplied in large quantities within a few weeks of [illegible]e mentioned, but it was [illegible] until 1916 that a [illegible]sion was arrived [illegible] the matter; meanwhile, [illegible]ated, involved the nation in a loss of 200,000,000*l*.

A similar striking example of officialism occurred in relation to the Pomeroy bullet, which was eventually successfully used in attacking Zeppelins. This bullet had been first tried in 1908, and gave satisfactory results; it was submitted to the War Office in 1914, but rejected. In June, 1915, another trial was made of the bullet, and again it proved satisfactory; however, it was not accepted and brought into use until the autumn of 1916—that is to say, the country had to wait two years for the adoption of an essential missile which was urgently wanted, in spite of the fact that the efficacy of the invention had been unmistakably proved many years previously.

Instances of official ineptitude and bureaucratic formalism similar to those referred to in the foregoing examples, and others mentioned in Sir Percy Scott's autobiography, are, unfortunately, all too common in practically every Government Department in this country, and arise all from the same cause, the ignoring of the advice and opinions of the technical expert and a fixed distrust of him. Expression was given to this attitude a few years ago by an official of the administrative branch of a Government Department during an inquiry before a Select Committee of the House of Commons into an important engineering contract—a contract in which the technical staff had been entirely ignored at every stage connected with its negotiation. "I do not think," said this official, "these gentlemen, the highly technical experts, are suited, by their education or their environment and line of thought, and all that sort of thing, to decide very often what is the best thing to do. They jump to a conclusion." Yet the most superficial examination of the evidence that exists in relation to the measures and steps by which the technical expert has succeeded in providing man with the material comforts enjoyed by him, and by which there have been placed at the command of the business community the powerful aids to commerce and industry comprised in the domain of the public utility services, affords the most complete contradiction of the mischievous doctrine contained in the foregoing utterance.

It must not be imagined that it is alone in relation to questions of high policy, such, for

[2] Published by John Murray. Price 21*s*. net.

example, as the Dardanelles Expedition—with regard to which it is recorded in Lord Fisher's "Memories"[3]: "The Cabinet Council reached its conclusions without drawing the opinion of the expert thereat for its guidance"—that the technical experts are ignored; on the contrary, many examples can be given of instances when, in relation both to important technical aspects of departmental policy and to simple matters of executive detail, the advice of the technicians has been overruled or not sought.

The root cause of the mischief under discussion lies in the system of the Civil Service. A privileged class has been allowed to grow up there, a class which, by reason of its proximity to the Minister and of the long service of the individual members composing it in one particular office, has obtained too great an influence, and is thus enabled to exercise an ascendancy not only over Ministers, who flit through their Departments, but also over those officials whose early years are spent on executive and technical duties.

The remedy for the present unsatisfactory state of affairs as regards the position of the technical expert is not far to seek. As matters stand to-day, the technical staffs in the Government Departments have too little influence and authority, whilst the Civil Service clerk has too much influence and an excess of authority. The disparity between the powers of these two classes is a source of public danger, and the way to obviate it is by a thorough reorganisation of the Civil Service and its system. What is required is that the chief administrative posts shall forthwith cease to be a monopoly of the clerical staffs. A suitable organisation for the Civil Service would be one which provided that entrants into every branch of it should, as a rule, begin their careers in an executive grade, and be promoted to occupy administrative posts at the headquarters of a Ministry or Department only after giving proof that they were familiar with the practical aspects of the matters they might be called on to administer. By the introduction of such an organisation into the Civil Service, it would be possible to select the best qualified officers in each branch for the important administrative posts, and, in consequence, render possible the adoption of a system whereby all matters referred to headquarters on which decisions have to be passed would come invariably before those who were experts in the particular subject upon which action had to be taken.

Aeronautical Research.

Applied Aerodynamics. By Leonard Bairstow. Pp. xii+566. (London: Longmans, Green, and Co., 1920.) Price 32s. net.

IMPATIENTLY as we have waited for the publication of this book, we feel that its appearance could scarcely have been more opportune. For here, as we believe, will be found abundant evidence in support of those who, like the Committee for Education and Research in Aeronautics, have striven to resist the break-up of our aerodynamics laboratories and design staffs. Research is always costly, aeronautical research superlatively so; and a public whose ear has been somewhat dulled by the insistence with which its claims were urged—not always wisely—during the war is somewhat naturally deafened now, by strident calls for economy, to any temperate statement of its claims. It is not promises that are wanted at the present time, to justify further expenditure, but a record of things achieved; and although the tangible results of British science and invention, as applied to the construction of aircraft, have appealed, and by the glamour of long-distance flying are still appealing, to the popular imagination, yet it has resulted from secrecy necessary in war time that the foundations upon which these successes have been built—the patient, detailed investigations which have supplied our designers with the data they required—are familiar only to a very few, being for the most part contained in reports of which the circulation, no less than the appeal, has been limited to specialists.

Now, within one volume of reasonable dimensions and large type, we are presented with an authoritative review of the work achieved by our research organisations during five years of strenuous activity. We have no fears that impartial judgment will pronounce the time and expenditure to have been wasted. Most branches of applied science have developed rapidly under the stimulus of war conditions, but of applied aerodynamics it might without serious exaggeration be said that the science has been created. The pioneer work is done, but to those who read Mr. Bairstow's book carefully it will be evident that on every side lie fields for research of which scarcely the surface has been broken, and that no mistake could be more disastrous, if we acknowledge the importance of aeronautics, than a refusal now to avail ourselves of the experience acquired by those few men to whom its present state of development is due.

We do not, of course, imply that the book is

merely a record of war developments, still less an apologia for the aerodynamics laboratories. It is, both in intention and in effect, a handbook for the student, for the designer, and for the research worker, which assumes no previous knowledge in the reader, beyond the elements of hydrostatic theory, and illustrates the applications of aerodynamics in all its essential branches. Mr. Bairstow's qualifications for authorship are too well known to need description here. A leader in aerodynamic research at the National Physical Laboratory since the formation of the Advisory Committee for Aeronautics in 1909, his duties as expert adviser to the Air Board and Ministry during the war brought him into intimate contact with every side of aeronautical activity. Of great importance, in our opinion, is the fact that he has had first-hand acquaintance with research on both the model and the full-scale aeroplane, and so is entitled—whether we agree with his conclusions or not—to pronounce with authority upon the vexed questions which relate to "scale effect." But copious knowledge has not always, in the past, given us satisfactory text-books, and it is a real pleasure to find how well balanced is the structural scheme which Mr. Bairstow has devised. After touching lightly, but adequately, upon the early history of his subject, and having illustrated its present state of development by brief descriptions of typical modern aircraft and engines, he passes at once to a discussion of the principles of flight; and in his second chapter, within some fifty pages, the reader learns, by actual examples fully explained, how to make practically all the fundamental calculations required in estimating the performance and characteristics of aircraft.

In our opinion, this is one of the best features of the book. Aerodynamics is an empirical science, and design proceeds by the manipulation of experimental curves which, with rare exceptions, cannot be represented by mathematical functions; present-day developments consist almost entirely in refinement of the experimental data and of the methods of their manipulation, and thus have a tendency to obscure, for the general reader, the basic principles involved. By discarding all refinements, whilst extending his specimen calculations to cover a wide range of problems, Mr. Bairstow emphasises the fundamental principle that all design is conditioned by the experimentally determined properties of the wing section, and thus prepares his reader for an intelligent appreciation of the more detailed considerations which follow.

Chap. iii., which deals with experimental methods of measurement, as they have been in the aerodynamics laboratories, is characterised by the same breadth of view and neglect of unnecessary refinement. In it the reader, now initiated into the problems which the science of aerodynamics has to solve, learns how these problems are attacked on the experimental side, and what order of accuracy may reasonably be expected in their solution. The account given on p. 115 of the theory of model experiments on non-rigid airship envelopes might seem to suggest that the model scale should be chosen so as to give (in theory) *equality* of fabric tensions, whereas actually, of course, it is easy to obtain *proportionality* in a model of any scale, and increase in scale has the advantage that it reduces the error introduced by the weight of the fabric. Again, we could have wished that some description had been included of the "cascade" experiment on aerofoils, which seems so promising a line of development for propeller theory; but from a footnote on p. 290 we gather that the technique of this experiment had not been fully worked out at the time of writing.

Considerations of space prevent us from dealing as we could have wished with chap. vii., an admirable *résumé* of the investigations which have been made—without very much result, so far, as regards their practical application—into the theory of fluid motion, and with chap. viii., in which the author states his present position on the question of "scale effect." Not long ago this was a question which divided aeronautical experts into two fiercely warring bands: but the heat of that battle has since died down, and we imagine that few will take exception to Mr. Bairstow's summing up of the position. Scale effect, or at any rate its possibility, is indicated by theory; it is proved beyond question to exist in many of the problems which can be investigated in wind-channels; and it may very well be present to a troublesome degree in many of the problems which concern the complete aircraft: but the order of accuracy hitherto attainable in full-scale work is too far below the ordinary standard of wind-channel work to justify us in attributing to scale effect every discrepancy which has been discovered in the comparison of model and full-scale data.

The remainder of the book, which analyses and applies the design data from the aerodynamics laboratories, scarcely affords suitable material for criticism on a first reading; ultimately these chapters must be judged by the service which they render, in daily use, to the design office and the laboratory. We shall content ourselves by mentioning one particular in which, as we believe, the book could be improved in a second edition. We do not think it is merely

a personal preference which has been disappointed by the scantiness of the references in this volume to original sources of information, and to authors; in our opinion, the more authoritative a book is, the more importance attaches to complete references, whereby the reader is assisted in pursuing his investigations into any particular question which interests him. We hold, too, that the mention of authors' names is important for other reasons than the mere gratification of their personal vanity; it is an aid to memory and to verbal discussion (how otherwise—to take examples at random—shall we attain to the definiteness of meaning which we associate with "Lenz's law," the "Rankine cycle," "Bernoulli's equation," or the "Willan's line"?); and it is of enormous assistance to the reader in helping him to fit each new fact or theory into his mental picture of the scientific structure. We might add that consistency demands either the suppression of all references to individuals (which is no longer thinkable) or the adoption of the course which we advocate: no one would accuse Mr. Bairstow of partiality (and if a refutation of the charge were wanted, it could be found in the entire absence of all reference to his own part in the work which he describes), yet we have been struck by the apparent arbitrariness with which authors' names have been included or suppressed. We are conscious that it would be very difficult to give complete references at the present time, mainly because of the unfortunate preference for anonymous reports which was so prevalent in the early days of the war; but this difficulty should be removed by the publication of the reports in their final form, and we shall hope then to see those additions which will make this book the standard work of reference in its subject.

The printing and paper of the book are good, and a special word of praise is due to the illustrative diagrams, which appear to have been re-drawn specially for this work. The book is thick and rather heavy, and those who will make it a work for daily reference will probably find it desirable to clothe it in rather stronger binding.

Gymnospermic History.

Fossil Plants: A Text-book for Students of Botany and Geology. By Prof. A. C. Seward. Vol. iv.: *Ginkgoales, Coniferales, Gnetales.* (Cambridge Biological Series.) Pp. xvi+543. (Cambridge: At the University Press, 1919.) Price 1 guinea net.

TO every science, works which bring together the data of the subject are essential, and to none more so than to palæobotany, which is based on the correlation of fragmentary remains from all countries and of all ages. Prof. Seward has served his science well in completing the almost Herculean task of writing a text-book covering the whole field of these plant remains. The first volume appeared many years ago, and this, the fourth, is the final one of the series.

This disappointingly closes with the higher Gymnosperms, the series of plant families treated, and the author does not propose to continue the work so as to deal with the flowering plants. This is perhaps scarcely surprising, as the data bearing on the flowering plants are very complex and of a fragmentary and unsatisfactory nature, and have, moreover, been little studied in this country. Some up-to-date handling of the Angiosperms is greatly to be desired, and students will await with some impatience the appearance of the independent work Prof. Seward promises, in which he proposes to deal with the generalities of plant distribution, taking the fossil Angiosperms into account.

Prof. Seward's text-book should be a useful tool, not only to palæobotanists in particular, but also to all students of either botany or geology in general. Somewhat lost sight of in the mass of fossil species, there are, prefacing each group, excellent accounts of the living representatives of each family.

In a volume of such laborious detail as the present one, which appeals to the specialist rather than to the average layman, there must, of course, be many comparative trifles which tend to sidetrack any critic by inducing an attempt to deal with minor controversial matter. To do this, however, in a general review would be both ungenerous and unfair, because the amount of public recognition and the gratitude which scientific authors receive is small and out of proportion to the labour and to the sacrifice involved in their tasks.

Misprints are remarkably few, and the general perspective of presentation is well preserved, although here and there the author has naturally indulged in rather longer descriptions of one or two individual species which are first published in this book than such specimens would be allowed had they been published separately at an earlier date. It is doubtful, as a matter of general policy, whether a text-book is the place to publish new species at all, although any research worker must have in his notes records of small and relatively unimportant species which scarcely deserve independent memoirs, and the temptation to put them in the text-book must be very great.

Knowledge of the higher Gymnosperms largely depends on petrified material of secondary timber, for although fragments of foliage impressions with a few cones are known, they are compara-

tively rare. The Mesozoic and Tertiary rocks, however, are rich in silicified and other petrified woods, many of which belong to the coniferous genera. The determination of these woods is a particularly difficult branch of palæontological research, demanding great patience and knowledge of the finer points of plant structure. Wood determinations are often—indeed generally—neglected, owing to the difficulty of mastering the technique; but, as Prof. Seward truly says, "the student cannot afford to neglect this line of inquiry if he desires to obtain a comprehensive view" of the essentials of palæontological plant history. In the present volume a considerable proportion of the space is allotted to the careful and critical consideration of the species based on secondary wood. The terminology of this section is not entirely that adopted by other leading workers in this field, but tends perhaps to simpler grouping of the subject by the elimination of certain "genera" which are based on distinctions too subtle for secure determination, such, for instance, as the Phyllocladoxylon of Gothan. The elimination of doubtful genera, principally those which have names suggestive of affinities remote from those with which they properly are really to be associated, on the whole tends towards the clarifying of the science.

In conclusion, one can only urge every geologist and every botanist not only to possess himself of Prof. Seward's text-book, but also to acquaint himself with its contents.

The Nature of Musical Sound.

The Foundations of Music. By Dr. Henry J. Watt. Pp. xvi+239. (Cambridge: At the University Press, 1919.) Price 18*s*. net.

THE author unfolds a new theory to account for the fact that certain combinations of sound, called concords, are "pleasant," while others, called discords, are "unpleasant." In place of the ancient theory by which the "harmony of numbers" in the sense of proportions of string-length to pitch has dominated these questions since the days of Pythagoras, he considers that sound possesses "volume," an attribute somewhat difficult to grasp at first sight. So far as we can understand the new theory, the volume of a low sound contains within itself the volumes of all sounds higher than itself; the proportions of the various volumes coincide with the well-known proportions of those of pitch. Hence the volume of the sound represented by C is exactly double that of the next C above it, and the volume of G, lying between the two, is two-thirds that of the lower C.

As the lesser volume is contained in the greater, there is "fusion" of volume when two sounds are heard together. This fusion being complete in the octave, the two sounds coalesce to such an extent as sometimes to be heard as one sound. We are to understand, then (so far as we can make out), that the octave is the "pleasantest" interval. Next come fifths and thirds as pleasant intervals; and the discords, the volumes of which do not fuse with the root volume, are classified as "unpleasant" (pp. 24 *et seq.*), or words to that effect. We confess that this theory is so novel that we find it hard to grasp. To the musician a discord is not an "unpleasant" part of his raw material; it is simply a chord that requires to be "resolved" into a succeeding chord. It has, therefore, the element of motion, while the concord suggests repose.

The theory of fusion raises the ancient question of the prohibition of consecutive fifths and octaves. The author discusses at great length all the well-known attempts at explanation, and adds his own. Probably the prohibitions are merely conventions, as suggested by Cyril Scott, quoted in a footnote on p. 132. In the tenth century Hucbald says of the ancient organum of his day: "If sung with suitable slowness, you will see that it produces a sweet concord." The present reviewer, wishing to scoff at the notion that successions of fifths and octaves could "produce a sweet concord," asked the choir of the Plainsong Society to sing a specimen of tenth-century organum. To his and their surprise they found Hucbald entirely vindicated. And Dr. Watt shows (p. 84) that Gevaert, making a similar experiment at Ghent in 1871, found exactly the same result: "The impression made on the audience was profound."

The only example Dr. Watt gives in musical notation (p. 120) is a series of consecutive fifths by Karg-Elert, played very slowly on the softest organ stop. He offers an explanation of its "beauty"; we think, however, that the same passage, if sung or played rapidly and loudly, would be anything but beautiful.

Dr. Watt revives the old controversy as to whether the interval of the fourth is a concord or discord. We thought that musicians had long settled that the fourth from the bass, since it requires resolution, is a discord, while the fourth from any other voice is a concord, since it does not require to move.

The book ends with chapters on "The Objectivity of Beauty" and "Æsthetics as a Pure Science." To those wishing to investigate the nature of sound, its new outlook should prove interesting.

Science of Food.

(1) *Bacteriology and Mycology of Foods.* By Dr. Fred Wilbur Tanner. Pp. vi+592+10 plates. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1919.) Price 28*s.* net.

(2) *Food: Its Composition and Preparation. A Text-book for Classes in Household Science.* By Mary T. Dowd and Jean D. Jameson. (The Wiley Technical Series.) Pp. viii+173. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1918.) Price 6*s.* net.

THESE two books are very laudable attempts by our American cousins to place the important question of food on a scientific basis. The war brought home to people at large the importance of such study, but one hopes, in days of peace, not only that investigations will continue, but also that their application will be carried out to a greater extent.

(1) The first of the two books mentioned above is very complete, not only in the number of important foods dealt with, but also in the numerous methods of investigation described to detect impurities and prevent contamination with undesirable admixtures. It is the science of cleanliness in technical costume. The preface informs us that the work is written for those who wish to fit themselves for food control; but as it presupposes a thorough training in bacteriology and chemistry, we fear it will scarcely appeal to those who are food controllers here. What is really wanted is a book that he who runs may read, a book intelligible to the manufacturer, the packer, the tradesman, and the housewife. To present such with the graphic formulæ of, say, amino-acids and fats would be simply to terrify them. Still, the book should be useful to a more limited section of the population—namely, the analysts and bacteriologists. Its price strikes one as exorbitant even in these days of high charges.

(2) The second book is of a much more practical nature, and will be welcomed by all those engaged in the study of household science. It is an excellent chemical introduction to the science of intelligent cookery. The authors have taken care to provide themselves with a good preliminary knowledge of physiology and bio-chemistry, and if they go a little wrong in a few details, such as in their account of the vitamines, the slips are trivial, and do not affect their main arguments or their main endeavour, which is to rescue cookery from the domain of empiricism and ignorance.

W. D. H.

Our Bookshelf.

Petrology for Students: An Introduction to the Study of Rocks under the Microscope. By Dr. Alfred Harker. Fifth edition, revised. (Cambridge Geological Series.) Pp. viii+300. (Cambridge: At the University Press, 1919.) Price 8*s.* 6*d.* net.

A HEARTY welcome must be extended to this new edition of one of our most widely known geological text-books, which has had considerable influence in securing systematic and accurate descriptions of rocks by British petrologists. The present edition contains a few pages less than the previous issue, but this has been accomplished by diminishing the space at the headings of chapters and by the excision of superfluous notes and references to occurrences of minor interest, so that the value of the book is in no way diminished. New illustrations have been added, and the chapters on metamorphism largely re-written.

As in previous editions, the author rejects names given unnecessarily to local varieties, which he distinguishes simply by reference to the places from which the names were formed. This process might with advantage have been carried very much further. There is, however, already so much diversity in petrological nomenclature, not only in different countries, but also among individual geologists, that the author is probably wise in refraining from attempting any far-reaching reforms.

Perhaps in another edition a certain number of analyses of the more important rock-species might be included, as well as their specific gravities, which afford a valuable means of checking the determination of rocks in the field. J. W. E.

Chemistry and its Mysteries: The Story of What Things are Made Of, Told in Simple Language. By Charles R. Gibson. (Science for Children.) Pp. 246. (London: Seeley, Service, and Co., Ltd., 1920.) Price 4*s.* 6*d.* net.

HERE is another of Mr. Gibson's wonderful books for children. This time Mr. Gibson treats of the elements of chemistry, the conception of chemical constitution, combustion and respiration, electrolysis, spectroscopy, and "queer things" such as radium and liquid air. The author has not lost his powers of stating scientific propositions in simple and attractive form without departing (except in quite minor details) from the strictest accuracy. We confess that we had thought modern children rather more sophisticated and apt to regard as ridiculous analogies drawn from nursery games; but in this matter we bow to Mr. Gibson's judgment. His success in what he has set himself to do is beyond question; criticism, if any were offered, would concern rather his objects. But this is not the place to inquire whether it is really useful, or even harmless, to present the complex and highly theoretical conclusions of modern science without any serious attempt to present also the evidence on which they are based.

Neue Beobachtungen über den Erreger der Maul- und Klauenseuche: Die Entwicklung des Schmarotzers im Blut, speziell in den roten Blutkörperchen. By Dr. Hrch. Stauffacher. Pp. 62+plates. (Zürich, 1918.) Price 8 francs.

THE author describes and illustrates a number of curious linear and spherical bodies found in the red corpuscles of animals with foot-and-mouth disease, and works out a life-history for them along the lines familiar from the parasites of malaria. The difficulty in all such investigations is to be sure that the intracellular appearances represent the cause rather than the effect of the disease, and to distinguish between a parasite and some remnant of the nucleus of the erythroblast seems often to be impossible. Sometimes the nuclear remains are plain as such; sometimes by special methods they can be brought to take a basic stain in cells which by ordinary procedures would appear normal; it is quite possible that they may be thus unmasked in consequence of a parasitic illness. What curious objects may be found in red corpuscles is readily appreciated by examining the blood of a dormouse or of a new-born rat. The nail- or tadpole-like bodies shown very clearly in the first photograph are extraordinarily similar to those demonstrated some years ago by Braddon in (or on) the red cells in rinderpest.

A Night Raid into Space: The Story of the Heavens told in Simple Words. By Col. J. S. F. Mackenzie. Pp. 143. (London: Henry Hardingham, n.d.) Price 2s. 6d. net.

THIS book describes in a chatty, discursive way the elementary facts of astronomy. It is avowedly written for those who have absolutely no mathematical knowledge. Unfortunately, there is in many places an absence of the necessary precision of statement. Thus the description of precession suggests that it affects the earth's orbital motion, there being no mention of the equatorial plane. Moreover, the action is ascribed wholly to the sun, though the moon's contribution is twice as great. The description of sidereal time, and the explanation of the spectroscopic determination of radial velocity, are misleading. Also the erroneous statement is made that the Babylonian year contained 360 days, and had an intercalary month every sixth year. Its real length was 12 lunations, or 354 days, and there were 7 intercalary months in 19 years. Altogether the book needs careful revision; if this were carried out, it could be recommended as a simple handbook.

Musings of an Idle Man. By Sir R. H. Firth. Pp. xii+359. (London: John Bale, Sons, and Danielsson, Ltd., 1919.) Price 7s. 6d. net.

THIS book comprises seventy-five readable and suggestive essays on the most varied subjects, ranging from "The Origin of Life" to "Good and Bad Form." In an essay on "The End of Life" the author envisages the final destruction of life by heat due to radio-activity.

Museums and the State.

THE old danger arising from the haphazard application of a name surrounds the public institutions which are called "museums." By a perversion of its ancient signification, the word "museum" is now used to designate a collection of natural history specimens, pictures, antiquities, machinery, waxwork or other articles (rarely libraries), as well as the building where it is exhibited to the public either with or without charge for admission. There are various so-called "museums" supported by public funds, either national or municipal. The proposal to create a new body of Government clerks (or to aggrandise an existing one) on the pretence that museums form a "genus" which all alike require central control of one and the same "tape and sealing-wax" type, and that the well-known ignorant, and therefore impartial, Civil Servant is to have new fields of plunder thrown open to him—as "administrator"—is not surprising. We are familiar with such schemes, but, none the less, this is one that all serious lovers of science and of art should resist to the uttermost! What is needed in regard to our existing national and other public museums is not the creation of highly paid posts for otherwise unemployable "administrators," but definite legislation after inquiry and report by a Royal Commission as to the specific purpose, scope, and method of work to be followed in each of those great museums which in this country receive support from public funds. "Overlapping" of collections and neglect of this and that department could be at once prevented by assigning to each museum its proper function and by making its income depend upon its doing what it is intended that it shall do. No central salaried body, no "committees" of delegates, trustees, or members of governing bodies are required. They certainly would prove incapable and obstructive, as such "committees" have generally shown themselves to be.

The defects in the working of our national museums have arisen from the fact that they have come into existence in obscure, surreptitious ways and by chance—witness the history of the British Museum, of the Victoria and Albert Museum, and of the new so-called Science Museum. They have no programme, no clear assignment of scope and purpose to guide them, and no attempt is made by successive Governments to define their functions and to ensure for each of them and for other "museums" supported by public funds a reasonable system of management and control designed so as to ensure their activity and development as efficient instruments of public service.

A central bureau of managing clerks pretending to deal under a heterogeneous "committee" with all the various branches of science and art concerned in the life and progress of all our museums would be an exaggeration of the worst features of the present management by irresponsible and incapable "trustees."

I am convinced that what is needed is the separation and independence of the chief departments now agglomerated in the national museums and their redistribution to form a series of independent institutions each under its own highly expert specialist as director, with no other interference than that of a visitatorial board assigned to each museum, approved

by the Government, and reporting annually on the work and requirements of its own particular museum. Such an institution is Greenwich Observatory. Limiting my suggestions to the natural history sciences, I would have a separate "museum" for zoology and animal palæontology; another for geology (the study of the history of the earth's crust, *not* merely palæontology) with mineralogy and petrology, uniting the museum of the Geological Survey with certain portions of the British Museum; another for botany formed by the removal to the great and flourishing establishment at Kew of the botanical department of the British Museum; and another for anthropology and human palæontology. There seems to me no reason, no advantage, in mixing up the administration of these great centres of special study and research with one another or with the museum of ancient art, or for associating any of these with the great national public library.

Our museums are liable to suffer from the erroneous notion that their *chief* purpose is to furnish ready instruction to school-children and "the general public." Speaking with special reference to natural history, I think it will be admitted that (as in the case of precious records, antiquities, books, etc.) the main and most important function of a museum is the acquisition, study, and safe and permanent guardianship of specimens—specimens which are often unique or of extreme rarity and value, and form the actual evidential basis of the natural history sciences. This guardianship is necessarily to be associated with perennial study and development of the collections and abundant publication of finely illustrated monographs, catalogues, and descriptions by the museum director and his staff. These duties are, in spite of obstacles, performed in a highly creditable way by the present staff of the Natural History Museum, which, were it free from the dead-weight of an unsympathetic and irresponsible committee of trustees, would render even more abundant services to science and the nation.

In my judgment, the exhibition of the collections in galleries, through which the public may promenade or be personally conducted by itinerant lecturers, is a matter of *subordinate* importance. But it is one of great value to the public, and must be seriously taken in hand and dealt with wisely by the director of each museum. It is the simple fact that many (but not all) of the fine things in museums of natural history can readily be exhibited to the public so as to give pleasure and instruction, and it is desirable to enlist the sympathy and interest of the public by exhibiting with the greatest skill and judgment specimens so displayed and labelled as readily to attract attention and convey information suited to those who have no special knowledge of the branch of science in which the specimens have their place.

It is, however, of the utmost consequence that this kind of exhibition should be strictly limited in amount, and that what is done in the way of such exhibition should be the very best possible—the specimens most carefully chosen because they can be well seen and appreciated when in a glass case and without being handled, and because the information which they and others placed with them afford is of first-rate importance or of a specially fascinating character. It is a profound mistake to attempt to set out the mass of the contents of a museum in this way. Neither space nor skilful design and handiwork can be afforded for "exhibiting" huge collections in this style. The public is wearied and confused by too great profusion, and galleries which are needed for the preservation and study of collections by experts are liable to be sacrificed to the satisfaction of a mistaken demand for the setting out of a sort of high-class Noah's Ark through which a visitor may wander in a state of dreamy contentment, hypnotised by the endless stream of queer or brilliant things appearing and disappearing before him without any effort or comprehension on his part!

In any case, it is, I think, important not to allow the great public museums to become class-rooms for ill-provided schools. I should like to see the system which is used in the American Museum of Natural History in New York introduced. There is a large lecture-room in the museum, and courses of lectures on the contents of the museum, illustrated by photographic lantern-slides, are given by highly qualified members of the museum staff. Copies of the lectures and the lantern-slides are also supplied by the museum to schools around New York, so that pupils can be prepared by them beforehand for recurring visits to the museum. Though the specimens in a museum may be very thoroughly and well labelled, as in Cromwell Road, it is the fact that no method of insisting upon attention to a label has yet been devised. The public seem to be scared by labels. Nothing is so certain to secure attention as a man standing up in front of the visitor and telling him all about a specimen whilst pointing to this or that part of it.

The Natural History Museum has more of its collections in quiet study-rooms and less of them paraded in bewildering rows in show-cases than has any other public museum in Europe, so far as I know. But it has, nevertheless (in my opinion), too many galleries and cases given up to public exhibition. Even now (after the heroic efforts of Sir William Flower, in whose footsteps I followed in this matter) many of the cases are overcrowded and many are hopelessly placed as regards lighting, and should be abandoned as public show-cases.

There appears to have been no attempt on the part of the architect of the Cromwell Road museum to erect a building with the lighting or height and shape of galleries necessary for such a museum. The trustees were neither consulted in the matter nor competent to give an opinion if they had been.

I should wish, in conclusion, to refer any readers of NATURE who may wish to see a little fuller statement of my opinions concerning the scope and methods of "museums" to the chapter on museums in my "Science from an Easy Chair," second series, 1913, pp. 310–29.

E. RAY LANKESTER.

I CORDIALLY welcome the suggestion in the leading article in NATURE of March 11 that the Natural History and other science museums should be placed under the Department of Scientific and Industrial Research. For this Department to take over the Natural History Museum, the Science Museum, the Museum of Practical Geology (and the Geological Survey), and Kew Gardens there need be no change in its constitution. No Royal Commission need be invoked, for the Department would be merely undertaking duties for which it was formed, these institutions being the depositories of most of the basal collections, the facts, upon which much of science is founded. The administration of all could be carried out under one scheme, since the work of all is akin, and the men required to recruit their staffs are drawn from the same class of university men, having similar early training, with diverse specialisations later on.

The present condition in the above museums is most unsatisfactory in respect to differences in the pay and position of their staffs. Thus, according to Whitaker, the assistants at Kew and in the Science Museum start at 300*l.* a year, while geologists and naturalists with similar training start in the two others at 150*l.*; all have war bonuses at present. At Kew there are

eleven in the lower grade (300*l.*–500*l.*) and three above; in the Science Museum the numbers are three and six; and in the Geological Survey twenty and ten. In the Natural History Museum there are thirty-two graded up to 500*l.* a year as against eight above. The position in the latter is so bad that there has been a constant leakage for many years from its highly specialised staff into university and other appointments, the salaries in which exceed those paid in the museum. There is no abundant field of men with private incomes and natural history tastes upon which to draw. The fact that only about one man in four or five who join the staff can hope ever to receive an income above 500*l.* a year prevents any of the best students of universities from entering, while the museum, as the basal institute of several sciences in this country, demands the services of the best men, and of the best men only. The Natural History Museum is, furthermore, out of date in that, while the sciences it represents have advanced, it has taken little account of these advances; its staff has all the same duties as it had twenty or thirty years ago, and, still numbering the same, can undertake new duties only by neglecting older ones. It was never intended to be a museum solely for education and amusement, but the policy pursued in regard to it in the last twenty years has neglected its other sides in respect to research, and its assistants have become more and more the cataloguers, arrangers, and cleaners-up of specimens. The staff less and less takes part in the proceedings of scientific societies because it cannot afford to belong to them.

May I suggest that the pay, position, and grading of the staffs in all the above four institutions should be those of the Home Civil Service, and that the numbers in different grades should be the same as in that Service? The prestige and position of the Civil Service are such that it is an object of ambition to the boy, and no lower position will attract the picked students of science. J. STANLEY GARDINER.

Zoological Laboratory, Cambridge March 15.

THE timely leading article which appeared in NATURE of March 11 raises the very important question of the future administration of the national museums and art galleries of this country. With the main recommendations of the article I am in complete agreement. There is little doubt that the administration of the national museums and art galleries on federal lines from a central Government Department would make for greater efficiency and economy, obviate considerable overlapping, and lead to the fuller use and development of the unique collections housed within their walls. The Department of Scientific and Industrial Research has already assumed control of the Museum of Practical Geology, and the machinery, therefore, for the administration of the whole of our national museums is already in existence, and only requires adapting and expanding.

Such a central Museum Department could be of the greatest service to the provincial museums and art galleries of the country if extended to include them and link them all up in one comprehensive scheme. At present the provincial museums are isolated. There is a lack of co-ordination and co-operation in their work, and they need the advice and assistance of a central body to help them in their development. The national museums between them cover the whole field of museum activities, and their amalgamation into a federal scheme would provide a Department able to deal with any branch of museum work, and to render invaluable assistance to the provincial and private museums throughout the country.

The National Gallery and the Tate Gallery would supply the nucleus for fine arts, the British Museum (Bloomsbury) for pre-history, anthropology, antiquities, and numismatics, the British Museum (Natural History) for natural history, the Victoria and Albert Museum for industrial and applied art, and the Imperial Science Museum for applied and technological science.

It is sufficient to indicate one or two ways in which the assistance of such a Department would be of the highest value:

(1) In the development of a comprehensive system of circulating collections for all branches on the same lines as is now done for industrial art by the Victoria and Albert Museum. (2) The provision of a staff of experts in all branches who could be placed at the service of museums for specialist work on collections. (3) The provision and circulation of approved casts of important and rare specimens. (4) The standardisation of museum cases and fittings to allow of their production on a cheaper and more efficient scale.

A Department such as I have indicated, linking up all the museums into one comprehensive scheme, would lead to the co-ordination of museum work throughout the country. The resources of the museums for each and every available line of research would be accurately known. The provincial and private museums would benefit enormously by having their collections accurately identified and labelled, and be able to utilise and develop their collections to the best advantage. By means of the circulating collections the vast resources of duplicate and reserve material in the national museums would be rendered available and accessible to the nation at large.

The cost of such a scheme would not necessitate an undue burden being placed on the State.

(1) The Government museums are already provided for by direct appropriations. The extension of their work on the lines I have indicated would necessitate larger staffs, but the labours of each expert would not then be rigidly confined to the one museum to which he was primarily attached. While the plan would require organisation and co-operation, it does not seem to involve any drastic change in the present management or governance of such museums.

(2) The public museums of the country could remain, as at present, under the control of the local governing bodies, and their financial resources be provided, as now, by the levy of a rate.

(3) Private museums would need financial assistance from the State, and this might be given in the form of grants-in-aid based on the amount of money provided by the resources of such museums.

The institution of a central Government Department would naturally necessitate Government control and inspection of museums, but such control, wisely and judiciously exercised, would stimulate their development. The Department should clearly recognise that its function would be to help and advise museums, not to hinder them by the imposition of irksome regulations. Museums should be encouraged to preserve their individuality and to develop along their own lines.

It is, perhaps, scarcely necessary to add that a central Department should have as its chief executive officers men trained in the various branches of museum work, whose very training and experience would give them the necessary knowledge to deal sympathetically with questions of museum administration, and to foster that spirit of research which is fundamental to the proper development of museums. W. M. TATTERSALL.

The Museum. The University, Manchester.

Organisation of Scientific Work.

I HAVE not read the report of Sir Thomas Holland's Commission which has led to a discussion in the columns of NATURE, and I do not wish to express an opinion on its conclusions. Those who know something of the conditions of India and of the many economic problems awaiting attack will at least agree that the country offers a great field for the investigator, and a difficult one from the point of view of those engaged in the administration of funds for research.

My purpose in writing is to support Dr. Russell's views on the importance of team-work in scientific investigations (NATURE, March 4, p. 7). It seems to me that in discussing the proper relation of the State to scientific work our conclusions will depend chiefly on the precise meaning which we attach to "research."

Prof. Bateson writes (*ibid.*, p. 6): "Research, like art, literature, and all the higher products of human thought, grows only in an atmosphere of freedom." But should not the word used here be "science"? Is not "research" the art by which knowledge is advanced? And is it not the case that in this art there is need for the co-operation of men differently endowed? "Bricklayers" may be wanted as well as "architects" in the building up of knowledge, nor are delays in programmes, other than housing, necessarily due to the lack of a plan.

If by "research worker" one meant only the "master," then I should agree with Sir Ronald Ross (*ibid.*, p. 6) that the policy of organising institutes for scientific research and institutes for the writing of poetry might be considered together. But research workers are not all "masters." There are other grades essential to progress in certain branches of knowledge, never likely to make great discoveries, perhaps, but, since the State needs them, it must enable them to live; and it is the function of the "official" not to direct their work (that must be left to the "master"), but to see that they live under conditions likely to promote efficiency. I am not sure that I agree with Prof. Bateson. There may be danger in State action, but it seems to me to be safer than inaction.

While arguing for the recognition of the importance of co-operation in research, let me add that, whatever part the worker in a research laboratory may be called upon to fill, it is essential that he should recognise clearly that he is part of a team for the advancement of knowledge, and that he should regard himself as a potential discoverer. I welcome Dr. Russell's analysis of the functions of the staff of an institution maintained for research, as it brings out what seems to me a fundamental point in this discussion, but I feel sure that he would agree with me in deprecating any rigid classification of workers as tending to cause discouragement. Whatever the natural qualifications of the members of a team of workers may be, two are essential for real progress: the desire to learn more and the willingness to help others.

Science and the New Army.

YOUR leading article of March 18 on "Science and the New Army" directs attention to some hopeful features in our future military organisation, but many will share with you the doubt whether any real fundamental reform has yet been effected. The new policy of "farming out" research work to civil institutions sounds suspiciously like the old policy, so well practised in the past, of getting technical work done and advice given without the obligation of paying anything for it. Doubtless it may be argued that so long as scientific men are complaisant enough to work for nothing a Government Department which paid them would be guilty of extravagance. Ultimately, however, it will be found good policy and sound economy to recognise that skilled knowledge is worth its hire, and scientific men, in their turn, may perhaps learn that in attaching a low valuation to their own labour they help to confirm the widely held idea that expert training is a thing of small account. The Army would keep more closely in touch with all scientific progress in any remote degree affecting the conduct of warfare—and who can set limits to this qualification?—if it retained men of proved competence with the duty of posting the General Staff in all such advances of knowledge. These men need not, in fact should not, give their whole time to the work; it would be an essential condition that they should be in full activity as researchers, teachers, or professional engineers, chemists, etc., and it would be equally essential that they should be remunerated at adequate rates. No unpaid committee, however august the membership, will fill the want.

I must confess that I scarcely understand what is ment by "preliminary design of apparatus," stated to be part of the functions of the military institutions. Of what value is a preliminary design if the underlying principles are not understood, and wherein does it differ from a mere statement of what some uninstructed amateur thinks can be done by "electricity" or by "cog-wheels"? Furthermore, unless these military institutions are directed by trained specialists, the "applied researches" entrusted to them are not likely to be crowned with any conspicuous measure of success.

E. H. HILLS.

Cotton-growing in the British Empire.

IN NATURE of February 26 Sir George Watt reviews in a critical spirit the report to the Board of Trade of the Empire Cotton-Growing Committee. Much of his criticism is based on an expressed aversion to committees, which has misled him into stating that we propose our central (cotton-growing) research institution should be staffed by a "committee of voluntary workers." This is quite erroneous. The report itself describes in some detail the permanent staff which is suggested.

Some of the criticisms are due to the reviewer not having realised that the Committee was dealing with cotton-growing alone, and that the British Cotton Industry Research Association is working in co-operation with the Empire Cotton-Growing Committee through a joint body (of which I happen to be chairman), so that his desire for the Cotton-Growing Committee to establish its central research institution in Manchester, where no cotton will grow, is invalid.

Nor do I think that his suggestion of a programme for the members of the research institution as being "research, education, and cotton production" makes a sufficiently clear discrimination between means and ends; but chiefly I regret that the reviewer has missed our main thesis, which concerns the need for knowledge, based on pure science, as the essential to progress in this matter. Indeed, he seems to be completely antagonistic to this view of ours when he states that "general principles of education must never be allowed to take the place of specific training and definite results." It is no little thing that a utilitarian body, representing all aspects of the cotton trade, from the native cultivators to spinners and manufacturers, should have come into the open with such a plea for the encouragement of pure science, as being the basis of useful development, and it is indeed un-

expected to find this plea condemned by a reviewer in the columns of NATURE.

Nevertheless, Sir George Watt makes a legitimate criticism when he says that our proposals "do not seem to resolve themselves into the promulgation of a concrete scheme of increased and improved production." I would like to explain why we deliberately avoided advancing such a scheme in this report.

The consideration of actual steps to be taken in cotton production is the next stage in the Committee's work, to which it has already settled down. When this report was issued we were penniless, and could not with any utility consider how money should be spent until we were assured of:—(a) Annual financial support from Lancashire. (b) Regular financial support from H.M. Government. (c) Approval of policy from the Governments of the Dominions, Colonies, and Protectorates.

Since our report was issued (a) the home industry has agreed to make a voluntary annual levy on itself; (b) our maintenance charges are assured, so that our executive can be built up, while the question of further support is under consideration; and official information as to (c) is awaited. A large income is already in sight, and the way is becoming clear for practical planning and guidance as distinguished from the enunciation of principles. It should be noted that the capital required actually to grow the cotton which this country now purchases outside the Empire is of the order of 250,000,000*l*., being more than a thousand-fold the sum asked for in our report.

But those principles had to be settled first, and I for one regret that Sir George Watt should have missed their significance through misunderstanding the present stage of our development and our inability to be anything else hitherto but a "committee," if we were to represent the native peoples abroad as well as the operatives at home, with all the intervening stages of industry, of administration, and of knowledge.

W. LAWRENCE BALLS.

Edale, Derbyshire, March 8.

I AM obliged for the opportunity given me to read Dr. Lawrence Balls's reply to my review in NATURE of February 26 of the report issued by the Committee on Cotton-Growing, within the British Empire, appointed by the Board of Trade. Dr. Balls seems to me, in the main, to admit my contention, namely, that the Committee's report, as it stands, does not resolve itself into a concrete scheme of increased and improved production of cotton. In fact, it may be said to be unfortunate that the Committee did not anticipate such criticisms as mine by giving the public some hint of the possible future stages of its operations. The public were anxiously awaiting a full scheme, and one that would give distinct prospect of success, but in place of getting such we are now told we have only seen (as it were) the first instalment, and must look for better results in the future.

But, turning to some of Dr. Balls's observations on my review, I do not find that I have stated that the report contemplates the staffing of the central research institution by committees of voluntary workers. It is surely self-evident that there would have to be permanent officials appointed to the central research institution, as also to the branch institutions. But what I did object to was that these officials should be put under a panorama of six committees, as seemed contemplated by the authors of the report. I am old enough to recollect the great Cotton Commission in India. Indeed, my official connection with that country might be said to have commenced with having to try to pick up the dishevelled threads of that futile expenditure of public money. The late Mr. C. B. Clarke, in the preface to his edition of Roxburgh's "Flora of India," alludes to the issue of one of the Commission's reports as follows:—"We have had plenty of Government and other reports, some very large and expensive ones, it is true, but we have very little economic work by persons competent as botanists; and with reference to one large and expensive report lately issued on an Indian economic plant it was discovered after it was printed that the Commission never learnt what the plant was."

The result of the great Cotton Commission of India was officialism, Cotton Frauds Acts, and other such futilities. It is the knowledge of past failures having very largely proceeded from officialism that makes me urge with all the earnestness I possess that the staff of the central and branch research institutions should be as free and independent as the professors of a university. They need no supervision more than is exercised by Departmental control in the allocation of funds and in the laying down of general rules and political instructions. Official control should be with the principal or principals of the college or colleges of cotton, but with no one else.

I am at a loss to understand Dr. Balls when he says I have missed "our main thesis, concerning the need for knowledge, based on pure science, as the essential to progress in this matter." The Committee, as I understood the report, recommends that certain universities should be asked to establish lectureships and readerships; my scheme was that the research institution or institutions, in addition to conducting research, should undertake the entire education of both the experts and the practical planters, and thus have their own professors of plant physiology, plant genetics, mycology, entomology, and the like.

My recommendation is thus to concentrate all effort in the hands of a body of highly trained scientific and practical experts, to place all the funds available in their hands, and to hold them responsible not only to increase the supply, but also to improve the quality of the cotton produced within the British Empire.

GEORGE WATT
(Formerly Reporter on Economic Products with the Government of India).

Annandale House, Lockerbie, March 13.

The Separation of Isotopes.

IN a recent discussion (*Phil. Mag.*, vol. xxxvii., p. 523, 1919) of a number of methods of separating isotopes Prof. Lindemann and Dr. Aston have shown that there is little prospect of effecting by the methods considered a separation which will yield pure samples of the isotopes in a reasonable time. Dr. Aston has recently announced the discovery that chlorine consists of a mixture of at least two isotopes having atomic weights 35 and 37. It appears that there is here a possibility of effecting a separation of the isotopes by a direct method which does not seem to be applicable in the case of most other elements. The method proposed depends on the assumption that in the absorption spectrum of chlorine, which contains a vast number of narrow lines, there is a difference between the wave-lengths of the absorption lines due to molecules containing different isotopes.

Supposing that ordinary chlorine contains the isotopes Cl_{35} and Cl_{37} in the ratio 3 : 1, the molecules will consist of $Cl_{35}Cl_{35}$, $Cl_{35}Cl_{37}$, and $Cl_{37}Cl_{37}$ in the ratio 9 : 6 : 1. It follows that if white light traverses a column of chlorine of such a length that the radiations absorbed by $Cl_{37}Cl_{37}$ are reduced in intensity by a factor $1/10^3$, the corresponding factors in the case of $Cl_{35}Cl_{37}$ and $Cl_{35}Cl_{35}$ will be $1/10^{18}$ and $1/10^{27}$ respec-

tively. Suppose that the light after passing through this column of chlorine enters a vessel containing a mixture of hydrogen and chlorine, which combine under the influence of the light absorbed by the chlorine, it would appear to follow that the initial rates of reaction for the molecules $Cl_{35}Cl_{35}$, $Cl_{37}Cl_{35}$, and $Cl_{37}Cl_{37}$ should be in the ratio $1 : 10^{9} : 10^{24}$. The hydrochloric acid thus formed should therefore consist almost entirely of HCl_{37} if the reaction is allowed to proceed for a suitable time.

If this experiment should prove successful, it would evidently be possible to prepare a "filter" from the chlorine thus obtained which would favour the formation of HCl_{35}. It is fully recognised that there are a number of factors which may affect the success of the experiment, which is now being tried; it is hoped that results will be obtained before long, but the method seems worthy of mention as involving principles which have apparently not been considered hitherto in this connection.

Calendar Reform.

Vous avez cent fois raison de souhaiter un accord pratique entre les partisans de la réforme du calendrier, et je vous demanderai, pour ma part, la permission de répondre quelques mots à votre judicieuse invitation.

On peut lire dans mon Annuaire astronomique pour 1920 que la réforme radicale que j'ai proposée en 1879, en 1884 et en 1891 étant trop difficile à réaliser, et l'humanité étant incapable d'accepter des solutions rationnelles en quoi que ce soit, nous pourrions nous borner à la simplification suivante:

1° Douze mois partagés en 4 trimestres égaux de 30, 30 et 31 jours, le premier mois de chaque trimestre commençant un lundi et le dernier jour du troisième mois étant un dimanche.

2° Le 1er janvier étant voisin du solstice peut être conservé. Ce serait, tous les ans, un lundi.

3° La fête de Pâques pourrait être fixée au dimanche 7 avril.

4° Les quatre trimestres égaux de 91 jours chacun formant 364 jours, il y aurait un jour de fête=0 pour les années ordinaires et deux pour les années bissextiles.

On aurait ainsi un calendrier perpétuel et universel.

CAMILLE FLAMMARION.

Paris, le 8 mars, 1920.

CALENDAR reformers will welcome M. Flammarion's alteration of his scheme to one which minimises the changes from the existing calendar, while it secures the removal of its anomalies and inconveniences. It would seem advisable to choose some day for the extra-week day that is already a public holiday. Christmas Day, New Year's Day, and Whit-Sunday have been suggested.

From the astronomical point of view the most important amendment is the placing of the leap-day at the end of the year, so that the interval from the beginning of the year to any calendar date is constant.

A. C. D. CROMMELIN.

On Langmuir's Theory of Atoms.

MR. S. C. BRADFORD's criticism in NATURE of March 11 of Dr. Langmuir's theory is scarcely justifiable, considering that the latter clearly states in his paper (Journ. American Chem. Soc., vol. xli., p. 868, 1919) that the equilibrium positions of the electrons are determined in part by magnetic, and in part by electrostatic, forces, the former necessarily implying electron rotations.

The electrons are probably rotating (some right-handedly, others left-handedly) in very small orbits about certain fixed points, *e.g.* the corners of each cube, the centres of such orbits being the positions of Dr. Langmuir's "stationary" electrons. Such rotations are exactly what is required for the explanation of directed valencies and the paramagnetic or diamagnetic properties of the elements. From magnetic considerations, Mr. Bradford's suggestion as to the nature of the rotation is inconceivable, since the one he prescribes would make fluorine and a number of other elements paramagnetic, contrary to experimental data. Moreover, the frequencies of such rotations, which he suggests might be identified with Bohr's spectral frequencies, would be affected by temperature changes.

Electrons rotating right- and left-handedly about definite points, in small circles the radii of which are small compared with the accepted radius of the hydrogen atom, appear to be necessary; but there is little possibility of reconciling such small orbital motions with the coplanar ones of Bohr, the radii of which are, under normal conditions, essentially of the conventional atomic size, and under certain conditions far larger.

University College, London, March 12.

Fireball of February 4.

ON Wednesday, February 4, at 6 p.m., a very bright meteor appeared in the sky at Naini Tal (India). It travelled from west to east at an altitude of about 60°, and was visible for fully five seconds. The yellow fireball left a bluish-white trail, which remained hanging in the air for a considerable time, and then gradually dispersed. About half-way through its course a big puff of vapour came out of the meteor, which probably indicated the bursting. Half a minute later a thundering noise was heard, which continued to rumble for a quarter of a minute. It had been snowing an hour before, but the sky was perfectly clear at that time.

M. L. DEY.

Central Chemical Laboratory, Naini Tal,
India, February 5.

IT is curious that on the same date a large fireball was observed in England at 6.14 p.m., but in this case the object moved from east to west, *i.e.* in a contrary direction to the one seen by Mr. Dey. It is, however, by no means rare that two or more fireballs appear on the same night, though they are seldom members of the same meteoric system.

W. F. DENNING.

Buzzards and Bitterns.

IN the *Times* of March 12 it is stated that "the Lakeland buzzards are extending their breeding range . . . and that a nest was detected in the Buttermere Valley."

It would thus seem that the buzzard was finding its way by instinct to a region where, in old times, it had obtained an easy prey in the bittern, which gave its name to the mere. The early name of the bittern was "butter," and a Buttermere is mentioned in a charter ascribed to A.D. 863 as occurring in Wiltshire. There are a number of place-names in the country involving the designation of the bird, although its "bump" is no longer heard, as by Tennyson's Northern Farmer.

Ostrich Study in South Africa.

By PROF. J. E. DUERDEN.

THE domestication of the two-toed ostrich in South Africa has rendered available for observation and experiment large numbers of a creature in many respects worthy the attention of zoologists. While this bird's lack of intelligence and absence of any personal recognition may discourage the lover of animals who looks for some response for care and attention bestowed, its towering size, wayward strength, and nuptial viciousness yet engender a wholesome regard. The high industrial importance which attaches to its plumage has made necessary an intensive study of the physiological conditions which influence feather growth, as well as of the genetical considerations which determine its advance. It is true that, as the foundation of an industry appealing only to adornment and luxury, the bird fell on evil days during the war; but the outlook for the future is now encouraging.

Though in the wild state the ostrich is one of the most nervous of birds, its instinctive fear of man the unusual can be kept in abeyance on the farm by close association and constant handling from the chick stage onwards, and with intelligent control it is rendered amenable to all the necessary restraints of domestication. Should neglect occur, however, the wild nature asserts itself, and restraint is afterwards impossible, irresponsive as it remains to any "breaking" process.

During the past fifty years or so the farmer has worked out the main conditions necessary for the production of plumage of the highest excellence, without, however, any concern as to the physiological principles involved. As epidermal outgrowths, growing at the rate of a quarter of an inch a day, the unripe plumes are found to be extremely responsive to any variation in the condition of nutrition of the bird. Even the slight difference of blood-pressure between day and night is often found to leave its impress on the growing feather in the form of an alternation of denser and weaker annulations, while, should the bird be in a reduced state, a kinking of the feather sheath at a ring of night growth may result in the formation on the opened plume of the familiar defects known as "bars" (Fig. 1). Reduced nutrition may even result in complete stoppage of feather growth, particularly in the case of chicks, a new plume pushing out the old on the restoration of better conditions. Of all parts of the body, epidermal structures seem the first to suffer from insufficient nutrition and to retain a more or less permanent impress of it, as is so often exemplified in nails, hoofs, horns, wool, and hair; but in the rapidly growing ostrich plume the response appears more manifest, and an economic importance attaches thereto.

The clipping of the plumes is no more harmful to the bird than is the cutting of the hair or the trimming of the nails to ourselves. They are taken as soon as opened out for fear of deterioration, while the quills are allowed another two months in which to complete their growth. Several helpful facts are disclosed on the extraction of the quills. Thus, the drawing of the quill invariably serves as a stimulus to the germ below, and the new feather appears at the lip of the socket in about a month's time. All being drawn simultaneously, a full, even crop of plumes is secured, each regular and perfect in its growth, owing to mutual protection—a great contrast with a crop from a wild or uncared-for bird, which is made up of plumes at all stages of growth as a result of moulting irregularities. Before maturity of plumage is reached, a feather drawn out of time is intermediate in character between those of the

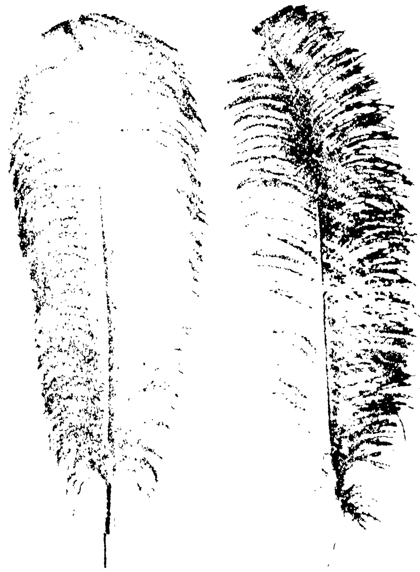

FIG. 1.—Ostrich plumes showing barring defects and sloping butts, results of reduced nutrition.

plumage before and those coming after. The time of quilling is the most critical of all the operations connected with the farming of the bird, as it determines largely the nature of the succeeding feather crop. The state of nutrition, sexual stage, period of the year, and climatic and food conditions have all to be considered. Where only a single clipping annually is secured, adult birds are, if possible, quilled at such a period as will bring the crop to ripeness about the beginning of the breeding season—that is, the middle of winter.

While the growing plume is highly responsive to changes of nutrition, the farmer soon discovered that the response was limited, and that with all his care only certain birds produced superior plumes. As in other domestic animals where much importance is attached to details of

form and production, great variations in the minutiæ of feather structure were encountered, all of which have a big industrial bearing. Scarcely any two birds produced plumage alike in character, and the whole object of the breeder has been to bring together in a single plume the best of all the characteristics distributed among the original wild stocks. Without any knowledge of Mendelism or of the factorial hypothesis, the ostrich farmer has clearly grasped the genetic distinctness of the innumerable "points" of the plume, and the impossibility of procuring those desired except from birds already exhibiting them. The best plumage birds in South Africa to-day are the product of only two or three original strains; all the rest have been discarded as breeders, through not showing sufficient merit. No new character or mutation in plumage has ever occurred since domestication. Selection in breeding is based on plumage alone, no bodily characters having been found to be correlated with it. It is manifest that any ostrich of weak metabolic activity would necessarily produce a defective plume also and be discarded on performance alone, however desirable the plume factors of the germ might be known to be; hence the farmer is more justified in selecting his breeders on production than he would be in selecting on pedigree alone. It is not much that the geneticist can do for the practical breeder in cases of this kind; he can, however, expound to him the soundness of the principles on which he is working and thereby encourage him in his efforts.

Along with the other members of the ratite group, the ostrich has long been regarded as in many respects degenerate or as undergoing retrogressive evolution. The relative smallness of the wings and the presence of only two toes to the foot are manifest features, but a closer study reveals many other directions in which loss has taken place, particularly in connection with the epidermal derivatives, scales, feathers, and claws. The thousands of specimens available provide ample material for observing the various stages in the process and the manner in which the loss proceeds. In such studies it becomes important to distinguish between diminution in size and the loss of constituent parts of a structure. Thus, although the wings are so disproportionately small, structurally they are actually less degenerate than in any other living bird. The first and second digits bear claws, and the third digit has sometimes a free second phalanx and may bear feathers. The outer toe of the foot is far less in size than would be expected of the fourth in the sauropsidan sequence, yet it retains all its five phalanges. Also, as showing the independence of the degenerative changes one of another, it may be observed that, though the wing is structurally less reduced than in other birds, the foot is unique in having only two toes; it is more degenerate than in any other living bird.

That a type has undergone degeneration in any respect can be established only by comparison with closely related members of the group to which it belongs, comparative anatomy affording us a safe standard. On this basis there can be no question of the various lines of degeneration represented in the ostrich, and if among the multitude of specimens examined differences of degree are met with along these lines, it is a fair inference that they represent the various stages of the process, and reveal to us the manner in which evolution proceeds. Whether the occurrence of these intermediate stages within extremes proves that evolution is actually in progress to-day may be a reasonable inference in the case of such an animal as the ostrich; but, as Prof. Bateson has pointed out, it can be definitely established only by comparisons at long intervals of time showing a general average reduction.

Comparing, then, the various stages in the degeneration of any particular feature of the ostrich, it is found that wherever a sufficient number of

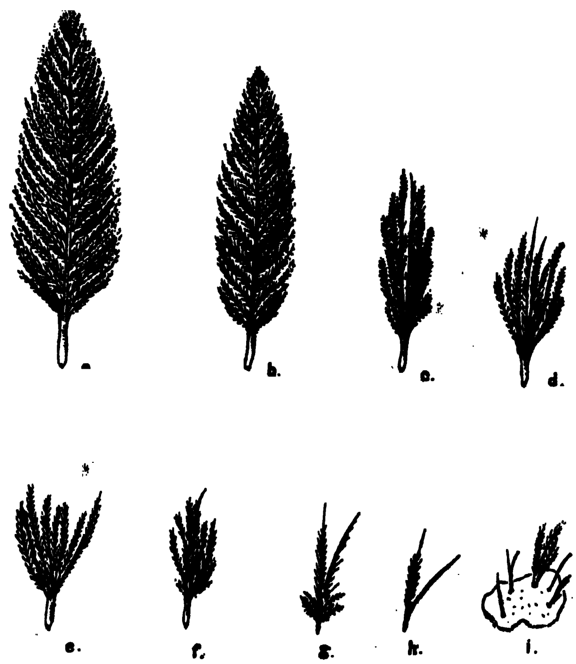

FIG. 2.—Series showing stages in degeneration of a feather.

individuals can be got together a continuous series is presented, linking up the extremes (Fig. 2). Thus birds are to be found with wing quills varying in number all the way from 44 to 33; the under-covering of down may be practically lacking, while all stages occur leading up to a feeble development over the greater part of the body; the under-surface of the wing may be naked with the exception of a much reduced single row of under coverts, but intermediate stages occur culminating in three rows of coverts; many degrees in reduction of the upper coverts are also encountered; the second phalanx of the third finger varies from a free distinct bone to a triangular vestige fused to the end of the first phalanx. On the little toe the claw varies from a stage where it is well developed to one where it is altogether absent, and the scutellation of the big toe may

either be continuous with that on the tarsus or show stages in "breaks" at one or two of the joints (Fig. 3). These and other facts of a like character go to prove that the degenerative evolutionary processes in the ostrich are all *orthogenetic* in their nature, and that a retrogressive change set up in any one direction is likely to be continued until final elimination of the part in question. The continuity is probably more apparent

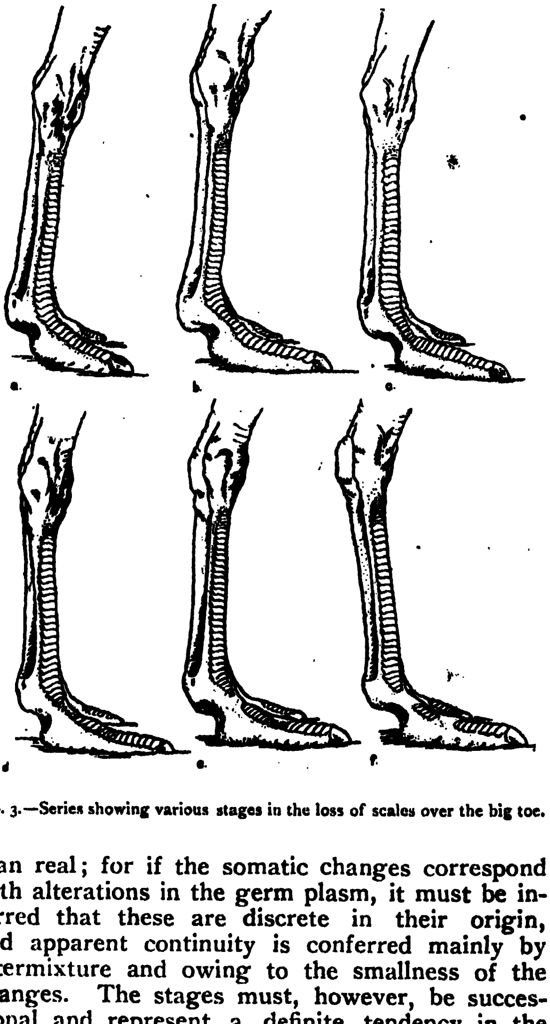

FIG. 3.—Series showing various stages in the loss of scales over the big toe.

than real; for if the somatic changes correspond with alterations in the germ plasm, it must be inferred that these are discrete in their origin, and apparent continuity is conferred mainly by intermixture and owing to the smallness of the changes. The stages must, however, be successional and represent a definite tendency in the germ plasm, in contrast to the haphazard nature of the mutations usually studied—a tendency which is held to be wholly apart from any considerations as to the welfare of the bird, as well as from environmental influences.

To the highly contentious question of the inheritance of acquired characters, the ostrich would appear to have a contribution to offer. Owing to the loss of its second toe, the crouching bird, for mechanical reasons, no longer makes use of the symmetrical axial callosity at the ankle, but develops an accessory one to the side. This is formed anew with each generation, and must have done so ever since the second toe disappeared, though presumably this happened thousands and thousands of generations ago. No hint of the accessory callosity occurs on the newly hatched chick; it is not inherited, but has to be acquired anew each time. On the other hand, the hereditary axial callosity, though unused for the same period, shows no signs of reduction; it has persisted through the ages, though non-functional. Further, the ostrich rests upon its sternal and pubic projections, and a strong callosity is developed over each. These would unquestionably form as a direct response of the skin to the pressure and friction involved in crouching, but are found to be hereditary, showing on the newly hatched chick. Hence we are presented with an hereditary structure which would also be formed independently as a result of the ordinary activities of the bird were it not already provided, strongly compelling us to suspect that the presence of the former is in some manner directly connected with the latter; in other words, that a character originally developed as a result of external stimuli has in time become so impressed upon the organism that it now makes its appearance apart from the primary stimuli.

The question of the origin of the three or four species of ostrich also makes some appeal to the evolutionist. No one intimately acquainted with the northern and southern ostrich would dispute their specific distinctness, but the East African and Somali species appear to be founded on intermediates of the two. Moreover, the northern and southern birds freely interbreed, and their offspring are fertile, some of the characters blending and others showing Mendelian segregation. Unquestionably all the representatives of the genus Struthio are a common stock, continental in their distribution, in which mutations have occurred in certain areas and not in others, but not of such a nature as to prevent free interbreeding.

The Conservation of Our Coal Supplies.[1]

By PROF. J. W. GREGORY, F.R.S.

COAL is the main material foundation of British industrial supremacy. The importance of coal is given by Mr. Justice Sankey as his first reason for its State ownership. The rapid British industrial progress at the end of the eighteenth century was due to our abundant coal. Modern coal mining began in Belgium earlier than in Britain, but British mines soon had the greatest output in the world. In 1800 they produced two-thirds of the world's coal, in 1860 the proportion was 60 per cent., and in 1913 the United States,

[1] Address to the Philosophical Society, Glasgow, on March 10.

Britain, and Germany together produced 87 per cent. of the world's coal. It was not until 1899 that the British output was surpassed by that of the United States; but, in spite of the ease of working of the American fields, our yield per unit of coal area is sixteen times as great as that of America. The British output of nearly 300 million tons is irrefutable evidence of the skilful organisation of the British coal industry and of the courage and capacity of the British miner.

This drain of 300 million tons a year inspires disquietude as to how long it can last. The first authoritative estimate of our coal resources was that of the Royal Commission of 1865, which estimated them as roughly 150,000 million tons. Later estimates have increased this amount to about 200,000 million tons, which would maintain the 1913 output for 600 years; the United States supplies would be maintained for 1500 years, those of Germany for more than 1500 years, while the coal fields of China would last for several millenniums. The world is in no immediate danger of a coal famine, but the British industrial position is threatened by the continued rise in the price of coal, which may hamper competition with countries with cheaper supplies. Jevons in 1865 issued a warning of this danger, and his main prediction has been amply justified, for during the seventy years from 1834 to 1904 the price of coal almost doubled, while that of general commodities fell by about a quarter. The increased cost of coal cannot, therefore, be explained by such influences as variations in currency.

The maintenance of the British output at a price which will enable British manufacturers to compete with those of foreign coal-producing countries depends on the increase of our coal reserves by the discovery of buried coal fields, such as doubtless occur under the younger rocks of eastern and southern England, while an extension of the Scottish coal fields may occur in north-eastern Ireland under the lava sheets of Antrim. The coal field of South Yorkshire and Nottinghamshire has been enlarged since 1905 by the discovery of 400 square miles of coal-bearing country, most of which is already being worked or developed. The eastward extension of this field is less than was expected by the Coal Commission of 1905, but its eastern and southern margins are still undetermined. The Kent coal field was found, in consequence of a geological prediction, during boring operations at Dover in connection with the Channel tunnel. Private bores for water have thrown light on the possible range of the coal in the south-east of England, but there are large areas which are unlikely to be tested by private enterprise. It is deplorable that they should be left unproved, as a few bores between the Nottinghamshire and Kent coal fields, and between London and Bristol, might lead to the discovery of very important additions to the national coal reserves. Such bores should be put down at the national expense, the cost, if successful, being charged to the area benefited.

As much light may be thrown on the distribution of concealed coal by private bores, the journals of all deep bores should be communicated to the Geological Survey and published either annually or, if desired by those who have paid for them, after an interval of ten years.

The national coal supplies will be increased by the working of deeper seams. The extreme limit of coal mining has been regarded as 4000 ft., but that depth has been greatly exceeded in metal mining, and 4900 ft. is the accepted Continental limit for coal mining.

The working of thinner seams is becoming practicable by the use of machinery and by working coal in conjunction with the adjacent clays; but the extension of thin-seam working would be hindered by a Government scheme for the nationalisation of coal. The nationalisation of all minerals, since clay and limestone often form the ground in large areas, would mean the nationalisation of the land. The nationalisation of coal alone would seriously hamper that combined working of coal with clay or limestone on which the development of thin-seam working is mainly dependent.

It may also pay the nation to arrange for the extraction of seams so thin that they cannot be worked at a profit, for if the labour be available the direct loss may be recompensed from the profits earned by the coal in other industries. It has often been suggested that to make our coal last longer the output should be restricted, but that policy, fortunately, appears now to have no advocates. The universal demand is for an increased output. Its restriction is opposed to the sound commercial principle, "Use an asset while you can." Unrestricted output is, however, justifiable only so long as coal is used economically. Great savings are possible. Sir George Beilby estimates that the average British consumption of coal per horse-power per hour is 5 lb., and that it should be no more than $1\frac{1}{2}$ lb., thus saving 56 million tons of coal a year. Greater saving appears possible by economy in the use of coal than from the numerous alternative sources of power, though resort to them will become necessary if coal prices rise.

Economy in coal is the most promising method of reducing the drain on our coal reserves. The country has used only about 6 per cent. of its total coal. Our coal supply would maintain the 1913 output for centuries, but if the annual output increases until, as some authorities expect, it is trebled, the handicap of high price may be on us in less than a century. By economy in coal consumption great industrial expansion is possible on the present output.

The essential factors with regard to the coal question are that no other source of power is available in this country on a large scale; coal is still indispensable, while it is limited in amount and irreplaceable; and, owing to the exhaustion of the more easily worked seams, a steady rise in price will continue, and probably at an accelerated rate. Ultimately the nation must enforce economy in the consumption of coal, prevent waste in mining, and be prepared to work seams at a

direct financial loss. The coal industry can be conducted on those lines in accordance with three possible policies—nationalisation, one coal trust for all the British fields, or group working by a combine for each coal field, co-ordinated by national control. Which of these policies is best is not a geological question. The problem for geologists is whether one of these policies is necessary at once, owing to the diminution of our coal reserves. The recent rise in the price of coal has been due partly to a just increase in miners' wages, partly to the higher costs of supplies, and partly to some spontaneous hypertrophy of price in distribution. Compared with these influences, the contribution to the soaring of coal prices by the geological factors is trivial. The conditions of our coal supplies do not render immediately necessary any drastic action in the conduct of the industry. In countries such as India, where the total coal reserves relative to the area and population are small, nationalisation may be the soundest economic policy, but we are far from the time when the three great coal-producing countries—the United Kingdom, the United States, and Germany—will find nationalisation necessary owing to the approaching exhaustion of their coal supplies.

The direct issue before the nation at present is between national ownership of the minerals with centralised Government control of mining—which may give us the drawbacks of nationalisation without its advantages, and is repudiated by both the miners and the mine owners—and a scheme of nationalisation combined with local administration of the industry by those engaged in it. The issue between nationalisation and the pre-war system may not be put to the nation unless as a result of the conflict between the nationalisers who advocate central control and those who advocate local control. The pre-war system has no chance of permanence unless developed to give the miners better conditions and a share in the control and financial fluctuations of the industry, combined with regulations to enforce economy in the use of coal and to secure less waste in mining, and with the determination of the extent of the concealed coal fields on which the future of the country will ultimately depend.

Obituary.

PROF. CHARLES LAPWORTH, F.R.S.

THE work of Prof. Charles Lapworth (who died on Saturday, March 13) in the sciences of geology and geography will continue to influence and inspire the growth of these sciences for many years to come. At the moment we can but mourn the loss of one worthy to be classed with the greatest of the old masters.

Gifted with a vivid and flexible imagination which he kept in his most brilliant excursions well under the control of his data, with unwearied patience in the collection of fact by his own observation or that of others, with an active and most orderly mind for grouping and arranging ideas, with the moral courage to hold his hypotheses in test until the survivors of them became proved theories, with a perfect genius for stratigraphy, an instinct for geometry, and the hand of an artist, Lapworth had the qualities requisite to bring the study of the older palæozoic rocks to the level of an exact science, to throw new light on the mechanism of earth-movement, and to forge the links between geology, "the geography of the past," and the geography of the present.

In 1864 Lapworth grasped the opportunity of work in the Southern Uplands, the country redolent of Scott, his favourite author. Spending every leisure moment in walking over ground thus made sacred to him, and possessing the gift of close and accurate observation, he could not help becoming interested in the landscape and the rocks; and he soon found himself studying the geology of the region in company with his friend James Wilson.

It happened that the landscape of this area concealed under an aspect of simplicity, but revealed to the eye of genius, a rock-structure of extraordinary complexity, to which there was apparently no clue except a few obscure pen-like markings, called graptolites, in the Moffat shales; and these had been tried for the purpose, but "turned down" as useless. Lapworth, however, determined to give them a second chance, and, as a result of systematic collecting, a keen eye for a country, and a retentive memory for minute, but significant, lithological variation, accompanied by a more elaborate piece of geological mapping than his predecessors had ever attempted, succeeded in proving that they could be used to unravel a rock-succession, even though it was more crumpled, inverted, and tangled than any other then known.

The rock succession and tectonic structure thus made out were tested against the simpler succession and relations and the more normal fossils of the Girvan area, and proved correct. At the same time, the graptolite zones that Lapworth had established were tested by comparison with successions made out partly by others, but mainly by himself at home, and by workers in Scandinavia, Bohemia, etc., proving that he had successfully performed at Moffat the double feat of working out the succession by means of the structure, and the structure by the succession.

The correct reading of the Uplands having shown that an apparently simple upward succession might be altogether misleading, and that this region gave support, and not contradiction, to general laws previously established in the organic and

inorganic world, suggested the probability that the varying interpretations of the Highland problem might admit of a like solution. While Lapworth was able to carry and apply his tectonic principles to the Highlands, definite organic succession now failed him, and he was driven to depend mainly on his stratigraphical methods applied to variations which were mainly lithological. Again, most elaborate mapping, and something akin to inspiration in the interpretation of it, came to his aid, and in a few months he had proved that the secret of the Highlands was that the region was the basal wreck of an ancient mountain chain exhibiting tectonic features akin to those worked out by Escher and Heim in the Alps. Lapworth was passing forward to the fuller study of the metamorphic area of the Highlands when his work was cut short by illness, and, in spite of his wish to do so, he was never able to take it up again.

The tectonic work, however, led on to the suggestive study of the rock-fold, which formed the subject of his address to the British Association at Edinburgh (1892), in which he passed from the structure of mountain chains to that of continents and oceans, and onward to the antilogous crests and troughs of the earth's crust as a whole, including that great "septum" the Pacific girdle of fire, the "wedding-ring of geology and geography." Later, Lapworth laid before the Geologists' Association his conception that a great continental wave sweeping round the earth would produce results analogous to those revealed by the succession of stratified rocks. In this, as in his other work, while possessing deep and sympathetic knowledge of the researches of such geologists as Suess, Heim, and Bertrand, he held steadily to the views of the mechanics of the earth's crust to which his independent thought had led him.

The success of his own graptolite work and the keenness with which it was being followed up by young observers led him to propose a new classification of the Rhabdophora, and to contemplate a monograph on the Order. This has now been completed by Miss Elles and Mrs. Shakespear under his guidance and editorship.

Although his duties at Birmingham, and the great amount of professional work involved by his position there, kept Lapworth fully occupied, his ideal diversion was always the discovery of new facts and their delineation on maps. Field classes, week-ends, and longer holidays were always devoted to this, resulting in the completion of large-scale maps of Nuneaton, the Lickeys, Dudley and the Coal-field, the Wrekin, the Longmynd and Caradoc, the Shelve country, and, last but by no means least, with his friend Dr. Stacey Wilson, the Harlech area. Little of all this work has been published. He loved to add to it, to improve and polish it, to fill in difficult corners in detail, and to show his treasures to his friends, delighting that they should realise some of the steps which led to his conclusions, and appreciate some of the labour of discovery.

As a great teacher Lapworth earnestly desired to equip his students to take their share in furthering the advance of science and to remove anything that could retard its progress. It was only fitting that the man who had stilled the Lowland controversy, and wrested its secret from the Highlands, should give the law in the "Silurian" controversy and make the opponents sink their differences by the adoption of his term "Ordovician."

SIR THOMAS P. ANDERSON STUART.

IT is with deep regret that we have to record the death, on February 29, in Sydney, of Sir Anderson Stuart, the well-known and highly respected professor of physiology in the University of that city, and the dean of its medical faculty. He had been in failing health for some months previously, but the fatal outcome of his malady was unexpected by his numerous friends.

Anderson Stuart was born at Dumfries in 1856, and was the son of Alexander Stuart, Dean of Guild. He received his early education at the Dumfries Academy, and later studied in Germany (Wolfenbüttel and Strassburg) and in the University of Edinburgh, where he graduated M.B., Ch.M. with honours in 1880. The next year he was appointed assistant of the professor of the Institutes of Medicine at Edinburgh, and later took the M.D. at that University, obtaining the gold medal.

It was in 1883 that Anderson Stuart went to Australia as professor of physiology at Sydney, which post he held until his untimely death. His was a forceful character, and he threw himself with enthusiasm into the work of teaching and research there. He will be remembered for many useful pieces of original work in connection with the circulation, the physiology of swallowing, and the eye. His various models and schemata, in which he manifested extreme ingenuity, are standard helps to teaching in all modern laboratories. His work as dean at a later stage in his career brought the medical school into high repute, and at the meeting of the British Association in Australia in 1914 he pointed out with justifiable pride the new buildings of the medical school, fully equipped with all modern appliances and accommodation for research and teaching, which formed the successful culmination of his efforts.

But Anderson Stuart was more than a professor, more even than a dean; he was a sagacious man of the world, and was appointed on many occasions delegate by his University to various international congresses, and consulted by the Government of New South Wales on many questions of public importance mainly related to educational problems. He was thus a well-known figure, not only in Great Britain, but also in other European countries.

In his adopted country Anderson Stuart's life was a long story of official appointments successfully discharged. He was twice president of the Royal Society of New South Wales. He was medical adviser to the Government of that colony,

and took a prominent part in all public health and educational movements; he was health officer to Port Jackson, president of the Board of Health, chairman of the board of the Royal Prince Alfred Hospital, trustee of the Australian Museum, and held many other public posts too numerous to mention. His activities in so many directions were recognised by the conferment of honorary degrees (M.D., Universities of Melbourne and Sydney; LL.D., University of Edinburgh; D.Sc., University of Durham), and finally by the honour of knighthood in 1914.

Anderson Stuart was held in high affection by his students, colleagues, and numerous friends in both hemispheres. He leaves a widow and several sons (who saw service in the recent war) to mourn his loss, and to them our heartfelt sympathy is offered.

By the death of Mr. J. S. MacArthur on March 16 industrial chemistry has lost a notable exponent. Mr. MacArthur's name will always be remembered in connection with the Forrest-MacArthur patent for the extraction of gold from its ores by means of cyanide. It is given to few men to discover a process which has had such a far-reaching effect in almost every branch of civilised life. The influence of an enormously increased quantity of gold available for mankind has been—as, indeed, it must be—profound, no matter whether it is for good or for evil. Compared with the huge sums of money involved, the amount accruing to Mr. MacArthur out of this patent was infinitesimal. His type was essentially a pioneering one. The initial work in connection with the extraction of gold was carried out with small funds in a laboratory which was in reality a cellar at the back of a Glasgow tenement house. After this work was completed, Mr. MacArthur engaged in many commercial ventures in connection with chemistry and mining, but, with the possible exception of his last, none of them seemed to possess the elements of permanent success. This was the extraction of radium from its ores, which he carried on first of all in Cheshire, and then practically on the shores of Loch Lomond, in order to avail himself of the purest possible water. He was proud of his works there, and delighted to feel that he was able to carry on his work in the midst of such beautiful surroundings. Mr. MacArthur's personality was delightful and genial. His travels had been world-wide, and to anyone interested in mineralogy and travel he was indeed entertaining.

Mr. James Procter, whose death occurred on March 6, was born in 1841. He took a prominent part in the design and manufacture of the engines required for blast-furnace work and iron and steel works, and is said to have been the first British engineer to construct blowing engines with mechanically controlled valves. Mr. Procter was a member of the Institution of Mechanical Engineers and of the Iron and Steel Institute.

Notes.

As president of the British Association at its meeting in Cardiff on August 24–28 next, Prof. W. A. Herdman, of Liverpool University, will deal in his inaugural address with oceanography, of which he will give a general survey, and discuss in detail certain special problems and recent investigations, with particular reference to the sea-fisheries. The following presidents of sections have been appointed:—A (Mathematics and Physics), Prof. A. S. Eddington; B (Chemistry), Mr. C. T. Heycock; C (Geology), Dr. F. A. Bather; D (Zoology), Prof. J. Stanley Gardiner; E (Geography), Mr. J. McFarlane; F (Economics), Dr. J. H. Clapham; G (Engineering), Prof. C. F. Jenkin; H (Anthropology), Prof. Karl Pearson; I (Physiology), Mr. J. Barcroft; K (Botany), Miss E. R. Saunders; L (Education), Sir Robert Blair; and M (Agriculture), Prof. F. W. Keeble.

In the interests of physiological and medical research, we may congratulate ourselves that the debate on the mischievous and unnecessary Dogs Protection Bill of Sir F. Banbury was "adjourned" on Friday last. Owing to the length of the discussion on the really important Early Closing Bill, that on the former Bill was prolonged until the rising of the House. It may be pointed out once again that no other animal of the size of the dog can be kept under laboratory conditions in a healthy state, and that the general chemical changes in this animal are closely similar to those of man, mainly owing to its omnivorous nature. The letter by Dr. Thos. Lewis in the *Times* of March 19 shows how obstructive the exclusion of the dog would be to one branch of investigation of great practical utility; and an equally strong case could easily be made out for many others. The report of the last Royal Commission on Vivisection shows that adequate provision against any possible cruelty has already been made, even if it were necessary to do so.

His Majesty the King has approved the award of the Royal medals of the Royal Geographical Society as follows:—Founder's medal to Mr. H. St. John B. Philby, for his two journeys in south-central Arabia, 1917 and 1918; and Patron's medal to Prof. Jovan Cvijic, Rector of the University of Belgrade, for distinguished studies of the geography of the Balkan Peninsula. The council of the society has awarded the Victoria medal to Lt.-Col. H. S. L. Winterbotham, for his exceptional services to the country in the initiation and development of scientific methods of artillery survey and the production of high-class maps of inaccessible areas. Other awards are:—Murchison grant to Miss Czaplicka, for her ethnographical and geographical work in northern Siberia; Cuthbert Peek grant to Mr. A. W. Pearson Chinnery, to assist him in continuing his work in the unexplored parts of New Guinea; Back grant to Mr. J. M. Wordie, for his scientific work on the Antarctic Expedition of 1914–17; and Gill memorial to Mr. Reginald Farrer, for his journeys on the Chinese borders of Tibet.

SIR JOSEPH LARMOR has been elected a corresponding member of the French Academy of Sciences in the section of geometry.

AT the meeting of the Royal Irish Academy on Tuesday, March 16, the following were elected honorary members in the section of science:—M. Henri Louis le Châtelier, Prof. George Ellery Hale, Prof. Augustus Edward Hough Love, and Sir Ernest Rutherford.

A COMMITTEE has been appointed to consider and report to the Minister of Transport on the question of the electrification of railways. The Committee is constituted as follows:—Sir Alexander Kennedy (chairman), Sir John Aspinall, Mr. A. R. Cooper, Mr. Philip Dawson, Sir Alexander Gibb, Mr. C. H. Merz, Sir Philip Nash, Sir John Snell, Sir Henry Thornton, and Major Redman.

THE Recording Secretary of the Nova Scotian Institute of Science has been good enough to inform us that at a meeting of the institute held at Halifax on March 8, on the motion of Mr. H. Piers, seconded by Dr. D. Fraser Harris, it was "resolved that the Nova Scotian Institute of Science convey to the publishers and Editors of NATURE, London, its congratulations on the occasion of the fiftieth anniversary of the establishment of that well-known scientific journal, and wish them continued success in the future." On behalf of the publishers, and for ourelves also, we thank the institute for its kind resolution of appreciation and trust.

A PROJECT for systematic exploration in Mediterranean oceanography was started at an international conference recently held at Madrid. According to *La Géographie* for January (vol. xxxiii., No. 1), the States represented were France, Italy, Spain, Greece, Monaco, Egypt, and Tunis. A commission was founded, with headquarters at Monaco and the Prince of Monaco as president. This commission will consider the methods to be adopted. Ships for the work are under construction or being planned by France, Italy, Spain, and Monaco. A beginning will be made this spring, France and Italy working in the Dardanelles and Monaco and Spain in the Straits of Gibraltar. The secretary of the central commission is Dr. J. Richard, Musée Océanographique, Monaco.

COL. VAN RYNEVELD and Capt. Brand arrived at Cape Town on March 20, and thus accomplished a flight along Africa from north to south. Three machines were used. The first left Brooklands on February 4 and was wrecked at Wadi Halfa on February 11. A new start was made from Cairo on February 22 with an aeroplane fitted with the engines from the first machine, and a flight was made so far as Bulawayo, where the machine crashed on March 6. On March 17 a machine was supplied by the Union Government to replace this, and with it Col. van Ryneveld and Capt. Brand completed their African air route of more than five thousand miles. Though not associated with scientific observation during the journey, the flight is a notable feat in the history of aviation.

DR. CHALMERS MITCHELL, in cablegrams from Dar-es-Salaam, published in the *Times* of March 15 and 16, graphically summarises his impressions on the physiography of the Nile basin as seen in his flight from Cairo to Tabora. His despatch depicts the unity of the processes which have moulded the surface of north-eastern Africa. The dominant features due to earth movements are being slowly smothered by sheets of sand and silt deposited in river deltas, in the marginal lakes formed where tributaries are barred entrance to the main river by the raising of its bed and banks, and in wide basins slowly being converted to plains by wind-borne dust. Dr. Chalmers Mitchell represents East Africa as having been cracked, whereas most other lands have been folded, and its vastest plains as due more to wind than to water. The lowlands are being filled by sub-aerial drift which buries the lower irregularities, and leaves the peaks rising abruptly out of the plains like reefs through the sand upon a shore. In the second part of his report Dr. Chalmers Mitchell refers to the beauty of the country, despite its aridity, and offers strong testimony to the progress which has been hieved in the Tanganyika territory, owing to "much ingenuity and vast expenditure of money, well laid out." His remarks on the elephants, giraffes, and antelopes observed during the flight show that the aeroplane would be of great service to sportsmen in the search for big game.

IT has frequently been suggested that the very heavy cylinders used for compressed gases are now out of date, and that the advances made during recent years in the science of metallurgy, particularly in connection with steel and its alloys, should enable a vessel to be produced which is lighter as well as safe. In consequence of these suggestions the Department of Scientific and Industrial Research formed a Gas Cylinders Committee in 1918, the members of the Committee being Prof. H. C. H. Carpenter (chairman), Prof. C. V. Boys, Prof. E. G. Coker, Dr. J. A. Harker, Major Cooper-Key, Prof. F. C. Lea, Eng.-Capt. J. McLaurin, Sir Charles Parsons, Major C. J. Stewart, and Prof. J. F. Thorpe. Compressed gases were much used during the war for various purposes, such as, for example, in supplying oxygen for airmen flying at high altitudes and for poison-gas warfare. Industrially also, in war, as in peace, there has been an immense development in the use of oxygen and acetylene for welding, of carbon dioxide and ammonia for refrigeration, of hydrogen for ballooning, etc., which no doubt will be maintained. Arising from the necessity of war, very light cylinders have been manufactured for the purposes above mentioned, and slightly heavier cylinders were made to an Admiralty specification. The Gas Cylinders Committee, in conjunction with the leading tube manufacturers, has made a number of tests of cylinders based upon these war specifications, and it is hoped that as a result of this work it may be possible to recommend the adoption of cylinders considerably lighter than those now in general use.

THE first engineering school to be established in London was that at University College. Since 1828

a succession of engineers have been educated there under an eminent series of professors, and it would be a thousand pities if its work in this direction were now to be cramped for lack of funds. The case was ably put by Prince Arthur of Connaught at a lunch at the Savoy Hotel on Friday last. His Royal Highness explained that the present scheme of extensions of the engineering laboratories of University College had a pre-war inception, and he paid a tribute to the valuable anti-submarine and other electrical research work carried out during the war by the professors at the college. The war had made us realise the necessity for adequate provision for scientific education and research, and he urged the need for the laboratories opened twenty-seven years ago by his father to be modernised and brought up to date. Twenty-four thousand pounds out of the 100,000*l.* which they were asking for had already been subscribed, including 10,000*l.* from Lord Cowdray in memory of his son, the Hon. F. G. Pearson, who lost his life during the war. Lord Cowdray had also promised a further 10,000*l.* when a total of 70,000*l.* had been collected. Dr. Russell Wells (Vice-Chancellor of the University of London) also emphasised the necessity for improved technological education for the future prosperity of the country, and announced further subscriptions aggregating more than 4000*l.* Sir Ernest Moir (honorary treasurer to the fund) supported the appeal, and Sir Robert Hadfield referred to the valuable research and educational work done at the college, which could not be continued without adequate funds. Sir Gregory Foster (Provost of University College) explained how important it was that the extensions should be put in hand without delay, and pointed out that, although the Government policy was to provide grants for maintenance purposes, capital expenditure had to be met entirely by voluntary subscription.

A PAMPHLET entitled "Currency Reform and the Need for a Nickel Coinage on a Decimal Basis," issued by the Decimal Association, directs attention to the recommendations in favour of decimal coinage which have been made from time to time by committees appointed by the Government to consider the question of currency reform. The simplification of account-keeping and of conversions of values into foreign equivalents which the introduction of a decimal coinage would necessarily secure is an advantage which would benefit the whole of our business community, and, in addition, effect a great saving of time in our schools. The Decimal Association is in favour of the pound-mil system, which retains our gold coins and replaces the present bronze coinage by new denominations of 4 per cent. lower value. The main objection to the alternative decimal systems is that they would impair the prestige of the pound sterling, which under the pound-mil system is retained intact. Proposed changes in the materials of our coins are now under consideration by the Government, and the pamphlet urges that the opportunity should be taken to get rid of our present inconvenient system and introduce a new coinage on a decimal basis.

THE second of the Chadwick public lectures on military hygiene was delivered by Gen. Sir John Goodwin, Director A.M.S., on March 15. The lecturer reviewed the Army hygiene during the recent war. The clothing served out to the troops was of the best, and special attention was devoted to feeding and rationing. The water-supply in large measure was subjected to chlorination in order to purify it, bleaching-powder being principally used for the purpose. Special measures were taken for cleansing purposes, bathing stations being established where the men bathed, and in the meanwhile their uniforms were sterilised and fresh underclothing was served out to them. Destructors were built, or extemporised out of biscuit-tins, etc., in which all the camp refuse was burnt. Special means were devised to prevent waste. Thus in the destructors all the solder from old tins was melted out and collected, and fat from the kitchens was saved and sent home for manufacture into glycerine and munitions. By these measures the health of the Army was preserved to a degree unknown in former campaigns. For example, in 1916, among a total strength of a million and a quarter of all nationalities, the number of cases of enteric fever was 0·2 per 1000 men, whereas in the Boer War the figure was 153 per 1000.

THE February number of the *Museums Journal* contains the report of a conference between Sir Amherst Selby-Bigge, Secretary of the Board of Education, and representatives of the Museums Association, headed by Sir Martin Conway, on the proposed transfer of museums to the local education authorities. The association presented a reasoned protest, laying stress on the fact that the educational activities of museums must necessarily be subsidiary to their primary function of collecting and preserving the works of Nature and of man, and to the study of this material in prosecuting "the highest aim of a museum . . . the advancement of science, art, and industry." It is the results of that study which eventually become available for the education of the public. The arguments in favour of linking up all the museums of the country with the national museums under the control of a separate museum board were advanced by Dr. Bather, who instanced among the prospective advantages of such an arrangement "the loan-circulation of natural history and other objects from the British Museum, the provision of expert help, and the cataloguing of the wealth of our scattered museums." Sir A. Selby-Bigge, in his reply, claimed that the conception of education had recently widened so as to include the chief functions which the deputation assigned to museums. The previous number of the *Museums Journal* reprints, with comments, the recommendations concerning the staffs of the national museums made by a Royal Commission, the report of which (Cd. 7338), issued in April, 1914, was obscured by the smoke of war.

A "SPECIAL Report on the Prevention of Venereal Diseases," by Dr. A. Mearns Fraser, Medical Officer of Health for Portsmouth, has recently been addressed by him to the Health and Housing Committee of the

Borough Council, and is worthy of the careful consideration of all authorities concerned with national health. Dr. Fraser urges that the highest aim of a health authority should be the prevention, not the treatment, of disease, and that the necessity for extensive provision for treatment is evidence of the neglect or failure of prevention. He shows clearly that the successful prevention of venereal disease by scientifically accredited means can be achieved only by the adoption of certain sanitary measures which are readily available and easily applicable. These measures consist in the use of a solution of permanganate of potash immediately after exposure to infection and of an ointment containing calomel. The provision of these disinfectants by any local health authority is not suggested, but the authority is recommended to take such steps as are necessary to spread the knowledge of the means of self-disinfection, so that those who insist on satisfying their sexual appetites by promiscuous intercourse may be instructed how to protect themselves from diseases which, when contracted, are notoriously so often communicated to innocent women and children. Since it is far more easy to disinfect men than women, it is rightly urged by Dr. Fraser that it is of the first importance to prevent the infective germs from entering the body of the male, for if one sex can be protected from infection venereal diseases will be well on the way towards extinction. The report gives ample consideration and reply to various objections which have been persistently made against the inclusion of venereal diseases in the category of infectious and preventable diseases which can now be dealt with on scientific lines.

A CURIOUS case of stone worship is described by Mr. H. A. MacMichael among the Tungur-Fur tribe in the Sudan (*Sudan Notes and Records*, vol. iii., No. 1, January, 1920). The stone is known as the "Bride's Stone" or the "Custom Stone." Rites are performed on marriage, at the circumcision of a child, at a birth, and when a high official visits the place. But that at marriage is, as the name implies, the most usual. After the marriage rite the pair are made to rub some blood of a sacrificed animal on the stone in the form of a cross. If they are too poor to afford this, they offer a piece of cowdung. Then they are taken to a neighbouring well, where the officiant takes a piece of mud from the pool, daubs it on the foreheads, shoulders, waists, knees, and loins of the couple, and binds some green grass on their necks, ankles, and wrists—all doubtless intended as a fertility charm.

LAST year the Norfolk and Norwich Naturalists' Society attained its jubilee, and we congratulate its members on their fifty years of good work. The very name of "naturalist" is in danger of extinction. Our pursuits are so specialised that we have ornithologists, marine biologists, and protozoologists who yet could scarcely be called naturalists. Another peril to the name of naturalist was brought about by Mr. Arthur Balfour's use of the word "naturalism" to denote what other people call "materialism." It would be a thousand pities to lose familiarity with this most honourable name of naturalist, or to pervert it to a false use. Happily, we are safe so long as the Norfolk and Norwich Naturalists' Society flourishes, and others like it. Its latest number of Transactions (vol. x., part v., 1918–19) is altogether admirable, with Mr. W. P. Pycraft's paper on "Some Neglected Aspects in the Study of Young Birds," Mr. Robert Gurney's "Breeding Stations of the Black-headed Gull in the British Isles," and Mr. W. G. Clarke's "The Fauna and Flora of an Essex Common." The whole issue is well illustrated and well edited; and Dr. Sydney Long, the society's hon. secretary and editor, says truly that new problems and new points of view continually arise. "It is to be hoped that members of our society may devote attention in the future to such questions as the limiting factors in the distribution of our flora and fauna, to the peculiar physical and biological features of our great asset, the Norfolk Broads, or even to such practical questions as the advancement of agricultural methods by the application of modern ideas on heredity and soil fertility."

THE Sumatran hare (*Nesolagus Netscheri*) is one of the rarest of known mammals. Hitherto only two specimens have ever found their way into a museum, and these are in the Natural History Museum at Leyden. Messrs. E. Jacobson and C. Boden Kloss are therefore to be congratulated on being able to describe four recently captured examples in the Journal of the Federated Malay States Museums (vol. vii., part iv.). The specimens were obtained by Mr. Jacobson after a long and almost hopeless search in south-west Sumatra. In its coloration this animal is remarkable, being broadly striped with dark brown on a "buffy or greyish" background, forming a striking pattern, which is admirably shown in two photographs of a living animal. The skin of this creature is so exceedingly thin that it was possible to prepare the specimens captured only after hardening in spirit. It is nocturnal in its habits, and haunts the remote parts of the forest at an altitude of from 600 to 1400 metres. Hence it is almost unknown, even to the natives. So far as can be ascertained, it would seem to live in burrows at the base of big trees or in holes in the ground made by other animals. Mr. Jacobson succeeded in keeping one of the specimens here described for more than a year, during which time it fed readily upon cooked rice, young maize, bread, and ripe bananas. But its favourite food in the wild state would appear to consist chiefly of the juicy stalks and leaves of different species of Cyrtandra, which plants form a large part of the undergrowth of the forests in which it lives. Repeated experiments showed that these plants were preferred to all others, and were consumed in large quantities.

THE *Philippine Journal of Science* (vol. xiv., No. 6) contains an account by H. A. Lee and H. S. Yates of the so-called "pink disease" which has recently appeared in the Philippines, spreading rapidly and causing serious stem- and branch-disease of citrus-trees. The organism is a well-known fungus, *Corticium salmonicolor*, which, though not previously reported upon citrus, is known to cause disease on rubber-trees (*Hevea brasiliensis*), cocoa, coffee, and

other plants, economic and wild, in the Orient, where it is now widely distributed, though in 1900 the disease was practically unknown.

THE Journal of the Franklin Institute for February contains the address on "Sound-ranging as Practised by the United States Army during the War" delivered at the meeting of the physics section of the institute in October last by Prof. A. Trowbridge, of Princeton University. The methods used were those developed by our own Sound-ranging Section, and are known to many of our readers. They depend on the differences of the times of arrival of the sound of a gun at six stations near the gun, and are both sensitive and instrumentally very accurate. The residual errors are almost all due to uncertain meteorological conditions at the time of observation. As compared with other methods of location of enemy guns, the American experience is summed up in the following numbers:—During a three weeks' rapid advance sound-rangers accounted for 21 per cent., and flash-rangers for 79 per cent., of the guns located. During the two following weeks, when the advance had been checked, sound was credited with 54 per cent., and light with 46 per cent., of the locations. These records are characteristic, and show that the Sound-ranging Section required a little longer to get into efficient action than the Flash-ranging Section.

WE have received a copy of the first volume of the *Chemical Age* (June–December, 1919). Besides more or less ephemeral matter, the volume contains a number of important articles possessing a permanent interest. Among these may be mentioned "The Chemist's Place and Function in Industry," by Sir Robert Hadfield; "Recent Developments in Industrial Catalysis," by Dr. H. S. Taylor; "The Commercial Synthesis of Organic Compounds from Acetylene," by Mr. M. J. Marshall; and "The Synthesis of Ammonia," by Dr. E. B. Maxted. A useful feature of the journal is the weekly account, with illustrations, of patent literature; this keeps the reader early in touch with advances made both in this country and abroad, and will be of value to the industrial chemist and the chemical engineer. It is satisfactory to find that the promising standard of the early numbers is well maintained in the later issues.

IT is more than a hundred years since Sir Humphry Davy first described his wire-gauze safety lamp to the Royal Society (1818). The chief use of the lamp has, of course, been in the coal-mining industry. Danger of gaseous explosions also exists, however, in various chemical works where inflammable liquids are dealt with, a frequent cause being the use of naked lights in the repair or cleansing of large holders in which such liquids have been stored. Even at some distance from the liquid a naked light may be dangerous, as vapour given off may render the atmosphere capable of propagating flame. Attention is directed to this fact in the Journal of the Society of Chemical Industry (February 28) by Mr. W. Payman, who advocates the use of some form of safety lamp where artificial illumination is required in such circumstances, and describes various forms of lamp suitable for the purpose.

ENGINEERS who have to solve problems based on the properties of steam, and especially those connected with steam turbines, will welcome a new alignment diagram constructed by Mr. D. Halton Thomson, and published in *Engineering* for March 5. The principal part of the diagram is based on Callendar's equations for the properties of steam, and by applying the principle of duality Mr. Thomson has succeeded in producing an alignment diagram which represents not only the simpler of the Callendar equations, but also the others not hitherto amenable to this treatment. The diagram has scales showing (*a*) the total heat of superheated or supersaturated steam, and also the total heat of wet steam; (*b*) the amount of superheat; (*c*) the dryness fraction; (*d*) the total entropy; (*e*) the hydraulic efficiency for multi-stage turbines during superheated or supersaturated expansion; (*f*) the specific volume of superheated or supersaturated steam, and also of wet steam; (*g*) the absolute pressure; and (*h*) the saturation temperature. An auxiliary scale gives the relation of the heat drop and the steam velocity, and the Wilson point is marked on the chart. A straight-edge laid across the scales gives the whole of the required properties at once. As an example of the kind of complex problems which can be answered in this way, we quote the following from the article:—In a four-stage turbine the steam expands in thermal equilibrium from 200 lb. per sq. in. absolute and superheat 100° F. to 1·5 lb. per sq. in. absolute; the stage efficiency is 0·65 and the reheat factor 1·045. Required the pressure, specific volume, and quality at the end of each stage. By no means the least interesting part of the article is an appendix showing the methods employed by Mr. Thomson in transforming the equations to the form desired.

DR. GRIFFITH TAYLOR, the Australian meteorologist, delivered during the war courses of lectures on meteorology to the Commonwealth Flying School and at the University of Melbourne, and as a result he is now publishing, through the *Oxford University Press*, "Australian Meteorology, with Sections on Aviation and Climatology." The volume will include chapters on the study of the weather chart, work at a small station, the peculiarities of the Australian rainfall, the special storms and hurricanes of Australia, actual procedure in upper-air research, the discussion of long-distance forecasting and the application of meteorology to aviation, etc.

IN the *Veterinary Review* for February (vol. iv., No. 1) Mr. Fred Bullock contributes an instructive article on the compilation of bibliographies. Full details are given of the proper manner of compiling a bibliography, and a number of examples of correct and incorrect references to journals and other publications are given and criticised.

MESSRS. CROSBY LOCKWOOD AND SON, 7 Stationers' Hall Court, London, E.C.4, have just issued a new select list of books published by them on chemical technology. A copy will be sent to any reader of NATURE post free upon application to this well-known firm of publishers of modern scientific, industrial, and technical books.

Our Astronomical Column.

THE TOTAL SOLAR ECLIPSE OF 1918 JUNE 8.—Vol. lviii., No. 4, of the Proceedings of the American Philosophical Society is entirely taken up with a discussion of the observations made during this eclipse. The photographs taken by the Lowell Observatory Expedition at Syracuse, Kansas, bring out very clearly the connection between the prominences and the coronal arches. It is pointed out that this connection is much easier to trace at sun-spot maximum than at minimum. Dr. Slipher's photographs of the coronal spectrum indicate that coronium is much more abundant in the equatorial than in the polar regions. Messrs. Jakob Kunz and Joel Stebbins were stationed at Rock Springs, Wyoming, and measured the total light of the corona by photo-electric cells. Comparison was made with the full moon through the intermediary of standard candles. Allowing for absorption by the atmosphere, the total light of the corona was 1·07 candle-metres, just half the value found for the full moon. Comparison of the corona with the sky near the sun before and during the eclipse showed that the corona gave 1/10th of the sky light (same area) in full sunshine, and six hundred times the sky light during totality. It is obvious that most of the illumination of the landscape during totality comes, not from the corona, but from the distant regions of the terrestrial atmosphere, which are outside the shadow. Endeavours are being made by Prof. Hale at Mount Wilson to detect the corona in daylight by the use of photo-electric cells.

Mr. John A. Miller, of the Sproul Observatory, describes some researches to detect motion in coronal streamers by comparing plates taken at different stations. Recessions from the sun of 90, 60, and 15 miles per second were indicated for three different streamers. Mr. Miller also states that the forms of many of the streamers can be explained on the supposition that they are projected matter acted on by a repulsive force.

A NOON REFLECTOR.—Prof. C. V. Boys describes in the *English Mechanic* for March 5 an ingenious little instrument which he states to be capable of determining apparent solar time within a second. It is essentially a transit instrument; a small mirror, ¼ in. in diameter, is mounted on an axis about 2 in. long, with cylindrical ends which rest in two Y's, mounted on a stand which is capable of being firmly fixed in a window of southern aspect. Full details and drawings of the various parts are given in the article, with instructions which should enable any person with a mechanical bent to construct it. Small movements for fine adjustment in level and azimuth are allowed for in the design. Some protecting cover and some means of fixing firmly after adjustment is secured are also demanded, as it is somewhat tedious and troublesome to adjust it with high accuracy. The mirror is so small that the reflection of the sun on the opposite wall is fairly well defined, like a pinhole image, and the author states that he has frequently been able to see large sun-spots clearly. There is a certain amount of penumbra, but by practising uniformity in observing either the inside or the outside of the penumbral fringe the time of transit of the sun's centre may be determined to a second. The meridian is marked by a line on the north wall of the room; the noon image of the sun may be brought to the same point at all times of the year by rotating the mirror axis in the Y's.

American Fossil Vertebrate Animals.

AMERICAN palæontologists are making good progress with their detailed studies and descriptions of the original type-specimens of the various species of extinct vertebrate animals found on their continent. Most of the first descriptions were necessarily hurried and superficial, often unaccompanied with figures, and they are scattered in numerous small publications. Later discoveries have indicated more clearly the features that are of special significance and need particular attention in each case, so that new descriptions are of fundamental importance for exactitude in the science. Realising this, Prof. H. F. Osborn has just completed a valuable work by bringing together a series of up-to-date technical descriptions and figures of all the type-specimens of fossil horses from the Oligocene, Miocene, and Pliocene formations of North America (Memoirs of the American Museum of Natural History, new series, vol. ii., part i.). He not only deals with every species on a uniform plan, but also discusses in ample detail the correlation of the various formations from which the fossils were obtained. Besides reproducing the original figures already published, he adds many more, and among these the pencil drawings by two Japanese artists are especially noteworthy. A series of new drawings collected to illustrate the evolution of the upper and lower molars of the horses is a welcome compendium.

Other fossil mammals are described and discussed in the sixth volume of papers on vertebrate palæontology extracted from the Bulletin of the American Museum of Natural History, 1915–17. We noticed some of these contributions at the time of their publication, and we are glad to have them so conveniently collected. Several notes on the mammalian remains of the Lower Eocene by Messrs. W. D. Matthew and W. Granger add to our knowledge of the type-specimens by comparison with later discoveries, which are described and illustrated in detail. The paper on the Eocene Notharctus by Messrs. W. Granger and W. K. Gregory is also fundamentally important for a discussion of the origin of the Primates. In another valuable memoir Dr. Gregory pursues this subject, and reviews our present knowledge of the fragmentary fossils which seem to afford some information as to the origin of man.

The skeleton of Diatryma, a heavy running bird 7 ft. high, from the Lower Eocene of Wyoming, is described by Messrs. Matthew and Granger as representing a new order of uncertain relationships. Some of the Cretaceous Dinosaurs described by Prof. Osborn are also remarkably bird-like; and the wonderfully preserved Corythosaurus described by Mr. B. Brown, though evidently an amphibious Dinosaur related to Iguanodon, has a bony crest which would make the outward shape of its head like that of a cassowary.

In the volume from the American Museum there are also some notes on the gigantic Dinosaurs related to Diplodocus, but a still more important contribution to our knowledge of these reptiles is Prof. R. S. Lull's detailed description of Barosaurus in the Memoirs of the Connecticut Academy (vol. vi., pp. 1–42, pls. i.–vii.). Barosaurus seems to have a longer neck and shorter tail than Diplodocus, but is otherwise very similar to the latter. The gigantic Sauropoda, indeed, are not easily classified, and we still need many more technical descriptions like that before us.

Some of the type-specimens of the Permian and Triassic reptiles are also redescribed and discussed by Baron von Huene and Mr. D. M. S. Watson in the Bulletin of the American Museum; but the most

striking recent addition to our knowledge is a fine skeleton of Dimetrodon from the Permian of Texas, described by Mr. C. W. Gilmore in the Proceedings of the U.S. National Museum (vol. lvi., pp. 525–39, pls. 70–73). Mr. Gilmore has restored the reptile as shown in the accompanying figure, and none of the proportions are hypothetical except the length of the thin end of the tail. The total length is about 7 ft., while the greatest height at the middle of the dorsal crest is nearly 5 ft. It must have been an agile reptile, and the serrated sabre-shaped teeth would be very effective for the capture and tearing-up of its prey. The feet have sharp claws. The remarkable crest on the back is formed by the projection of the greatly elongated neural spines of the vertebræ, as in the existing little lizard, the basilisk, of tropical America, shown in the upper corner of our figure.

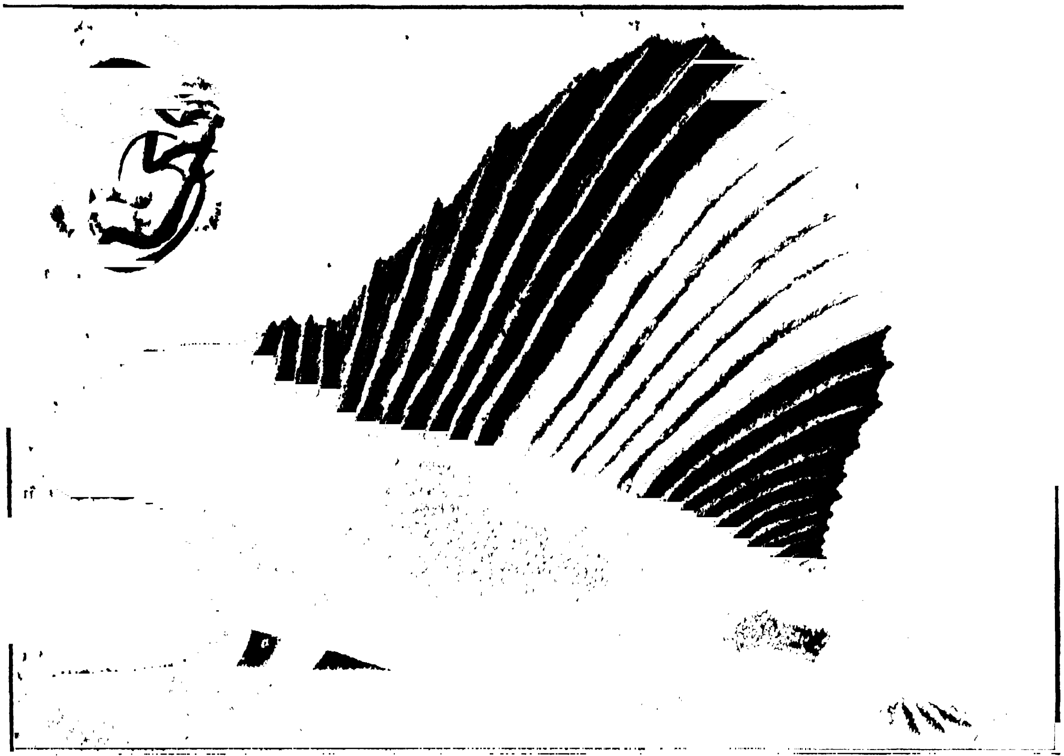

FIG. 1.—Restoration of a primitive carnivorous reptile, *Dimetrodon gigas*, from the Permian of Texas, made by Mr. Charles W. Gilmore for the U.S. National Museum, Washington; about one-twelfth natural size. Inset, the existing lizard, *Basiliscus plumifrons*, from Central America, showing dorsal crest formed by projecting neural spines.

The use of this crest is uncertain, but the most plausible suggestion seems to be that the reptile lived among scrubby vegetation, and the outgrowths, protectively adorned, may have helped to conceal it.

A. S. W.

Research in Textile Industries.

RECEIVING its initial impetus from the activities of the University of Leeds, later aspiring to wider activities in the West Riding of Yorkshire, the British Research Association for the Woollen and Worsted Industries has now attained to full status under the Department of Scientific and Industrial Research, and, according to the report for 1918–19 of the council, just published, may claim to be one of the largest, wealthiest, and most active of the associations under the Department. The annual income, apart from special donations and interest, is nearly 12,000*l.*, and it is hoped that ultimately the association will embrace the two thousand firms engaged in wool manufacturing in the British Isles. The outstanding feature of the year covered by the report has been the appointment of a director of research, Major H. J. W. Bliss having taken up his duties on March 24 last year.

Among the interesting matters dealt with in the report are the seven reports on researches or investigations undertaken by the association; the partial engagement of two specialists and the appointment of two investigators; the development of consulting work; the dissociation from the larger educational institutions—particularly the University of Leeds and the Bradford Technical College—and the start on the development of private laboratories at Frizinghall, Bradford; the institution of a library and information bureau and the indexing of past textile publications and research; the formation of two joint committees, one to deal with woollen carding and spinning, and the other with sheep-breeding; the receiving of deputations; and the formation of five local committees for England, Scotland, and Wales.

Reference is also made to the progress of research, especially in the United States and in Germany, attention being directed to the large sums of money spent and the large staffs engaged by individual firms, and the inference drawn that, large as the resources of the British Research Association are, they will have to be much augmented if the requirements of the wool industry are to be satisfactorily met. A little homily

is then given on "The Effect of Neglect in the Past," "Remedying the Neglect," "The Basis of Research," and "Research: What it is not."

It is to be regretted that the report shows a certain lack of appreciation of the conditions under which scientific research and investigations may be conducted. The appointment of a director who comes fresh and unbiased to the wool industry is an experiment well worth watching in view of future developments. But how comes it that the actual laboratories are to be divorced from the Yorkshire University of Leeds? This action appears all the more strange when it is noted that of the seven researches and investigations undertaken, five have been carried out in the University of Leeds; of the four appointments made to the staff, three are from the University of Leeds; and of the two large researches conjointly undertaken, both originated in the University of Leeds, the second being started by drawing upon the University's unique flock of Soay sheep.

It is further somewhat strange to read that "in the simplest matters it is not possible to find information in a correct and authoritative form," in view of the fact that the country which has been specially commended in the report for its highly developed research activities (the United States of America) adopts a Yorkshire text-book as its standard work of reference, and that Australia similarly regards Yorkshire publications on wool. We hope that the tendencies here indicated are only a passing phase, and that ultimately credit will be rendered to those institutions, particularly the University of Leeds and the Bradford Technical College, and individuals who by their labours in the past have made possible the development of this association.

Research work on wool presents such remarkable difficulties that apparently the only possibility of sound progress in the future lies in the closest and most amicable association of all institutions and individuals specially qualified to assist in introducing science and scientific method to the greatest possible extent throughout the wool industries. It may be that the secrecy insisted on by this association is essential in the interests of subscribing members, but the broader interests of research are represented by an approximately equal Government contribution, and it is obvious that these broader interests can best be fulfilled by a well-considered scheme of association between the educational institutions in question and the Research Association.

Climatology of North-west Russia and France.[1]

SINCE the withdrawal of the British Forces from Archangel and Murmansk, the climate of North-west Russia has become a matter of less interest to the average Englishman than was the case six months ago, but to the meteorologist the district remains one of importance. The climatic features of the area in winter must be considered in relation to its intermediate position between the relatively warm waters of the Arctic Ocean and the intense cold of Central Asia. The effect of these two influences is seen in the approximate equality of temperature in January at Alexandrovsk, near the mouth of the Kola River, in the north, and Petrograd in the south, notwithstanding a difference of nearly 10° in latitude between the two stations.

The comparative warmth of the Arctic coast is likely to become a matter of considerable economic importance, as it enables the recently developed port of Murmansk to be used for navigation throughout the year. The dates of the forming and breaking-up of ice on the Nova, Dvina, and Onega Rivers and on Lake Onega are shown in a table in the work under notice, where are given not only the mean date, but also the periods within which the date will occur on the average, (*a*) once in two years, and (*b*) once in five years, thus indicating the degree of variability experienced. This may be a matter of nearly as much importance as the actual mean value.

The climatic conditions of North-west Russia are presented in a series of tables giving data for seven stations, while letterpress directs attention to the more important features. It may cause surprise to learn that a temperature of 85° F. has been recorded at Archangel, while the average highest reading for July is 80° F. The percentage of cloudy skies in North Russia is high even in the summer—a feature which is well brought out by diagrams of a novel type, which show the frequency of fog, precipitation, and overcast, cloudy, and clear skies for Archangel and Kola.

Upper-air temperatures are presented for Petrograd, where trustworthy means are available, and also for Kiruna, in Swedish Lapland, where the number of observations is less satisfactory. In the two tables in which these data are set out, increasing height runs in one case up the page, and in the other down. It seems desirable that one or the other of these methods should be standardised. There is much to be said for reversing the older method and following the more natural way by running increasing heights up the page, so that the greater heights are above the smaller. The paper does not aim at being a complete treatise upon the subject of the climate of North-west Russia, but within a small compass a good deal of interesting information is put together.

The second of the two publications under notice is of a different and more specialised type, dealing with but one branch of climatology, namely, rainfall, for the southern and south-western districts of France. This forms the second part of a larger work which is to cover the rainfall of the whole of France, and, as the discussion of the data is left over until the publication of the whole is complete, the present volume contains little but tabulated matter. The region embraced is bounded by the Rhone on the east and by the Pyrenees on the south, while northward it stops somewhat short of the Loire.

The thirty Departments included in the area are represented by some 950 rainfall stations, the mean "density" varying in general in the different regions from ½ to 1 station per 10 km. square. In the main tables each Department is dealt with separately in the following manner:—First are set out brief particulars of the different stations giving height above sea-level and the period covered by the observations. Next are given the mean monthly and annual fall in millimetres for each station reduced to the common period 1851–1900. Finally, for selected stations the proportionate fall in each month of the year is shown. The means from these selected stations show the annual march of rainfall for the Department as a whole, and in this case correction is made for the unequal lengths of the months.

At certain stations, more numerous in some Departments than in others, the rain-gauge is placed upon a roof, which leads to an unsatisfactory exposure. It is pointed out that the errors introduced by such an exposure are proportionately greater in winter than in summer, so that the annual curve is distorted. It is worth noting that the normal height of the rim

[1] (1) "The Climate of North-west Russia." Pp. 26+4 plates. (London: Meteorological Office, 1919.)
(2) "Études sur le Climat de la France." Deuxième Partie: "Région du Sud-Ouest et du Sud." By A. Angot. Pp. 114+13 plates. (Régime des Pluies.)

of the gauge above the ground is 1·5 to 1·8 metres in France, so that a correction would be necessary before making comparison of the results with British records.

An excellent series of charts at the end of the volume indicates the rainfall distribution in each month and in the year as a whole. In the study of these charts one misses a contour map of the country. The annual fall varies from 500 mm. in two small areas on the shores of the Mediterranean to more than 1500 mm. in the mountainous regions. It is noteworthy that, after the Mediterranean seaboard, parts of the Atlantic coast take a high place among the driest regions of southern and south-western France. This is particularly the case in the summer months. A wise discretion has evidently been used in rejecting stations of doubtful accuracy in the preparation of the district means, and in other ways it is evident that trouble has not been spared to render the results as trustworthy as possible. J. S. D.

Volumetric Testing of Scientific Glassware.

ACCURATE work in the chemical and physical laboratory depends not only on the worker, but also to a large extent on the trustworthiness of his glass measuring apparatus, such as burettes, pipettes, and calibrated flasks. Whilst it is no doubt true that every operator who is master of his craft should be able, on occasion, to verify the accuracy of his measuring instruments, it is also true that both time and practice are required to do it well, to say nothing of the fact that special equipment is necessary for some of the verifications. Hence it is important, both to makers and to users, that facilities should be available for the testing of such instruments by experts, upon whose testimony reliance can safely be placed.

At the National Physical Laboratory apparatus of the kind in question has been tested, in respect of its accuracy, for the past fifteen years, but on a small scale only. Such instruments were mainly obtained from abroad in pre-war days, and it is only within the last two or three years that the making of them has developed appreciably in this country.

With the growth of the industry here it became necessary to make arrangements for testing and certifying glass volumetric apparatus on a larger scale than heretofore. Facilities were therefore provided and regulations drawn up, in co-operation with manufacturers and users of scientific glassware, for carrying out systematically what are known as "Class A" tests—that is, tests on apparatus required to be of the highest degree of accuracy. A pamphlet describing the arrangements and regulations was issued in July, 1918, and a new building has just been completed, with special equipment for dealing with this class of work on a large scale.

Instruments required to be only sufficiently accurate for commercial purposes are designated as "Class B." A permanent scheme for commercial testing of such articles by State institutions, or by other approved bodies, is now under the consideration of the Government. Pending the settlement of this scheme, manufacturers may note that the National Physical Laboratory is prepared to undertake "Class B" tests, which for the present will be carried out at Teddington. It is hoped eventually to arrange for this work to be done at local centres.

A full account of the methods of testing, limits of error allowed, details of construction, and fees charged is given in a new edition of the laboratory pamphlet, "Volumetric Tests on Scientific Glassware." Copies of this pamphlet may be obtained free of charge on application to the Director.

The "Class A" tests are designed for instruments intended to possess the highest degree of accuracy required in scientific use. Whilst the "Class B" tests are less stringent, the limits of error assigned are such as all graduated apparatus of good commercial quality should comply with, and are necessary for obtaining satisfactory results in ordinary routine analysis.

It is very desirable that the scientific glass-making industry developed in this country during the war should remain as a permanent asset. To attain this end the graduated apparatus produced should be not only well made, but trustworthy in respect of accurate calibration. From the maker's point of view, the advantage of having apparatus guaranteed by an impartial institution is invaluable for establishing a reputation for accuracy. As regards users, they will no doubt be glad to know that it is now possible to obtain apparatus the correctness of which has been impartially verified. The monogram of the National Physical Laboratory is the hall-mark of British scientific glassware so far as accuracy of measurement is concerned.

University and Educational Intelligence.

ABERDEEN.—Mr. W. G. Craib, formerly assistant at Kew, and now of the botanical department, Edinburgh University, has been appointed to the chair of botany vacant by the death of Prof. J. W. H. Trail.

BIRMINGHAM.—Mr. A. A. Dee has been appointed an assistant lecturer in physics.

CAMBRIDGE.—The governing body of Emmanuel College offers to research students commencing residence at the college in October, 1920, two exhibitions, each of the annual value of 50*l.* and tenable for two years and, on the recommendation of the student's director of studies, for such longer period as the degree course may require. The governing body may also make additional grants to students whose means are insufficient to cover the expense of residence at Cambridge or whose course of research may entail any considerable outlay in the provision of apparatus or materials. The exhibitions will be awarded at the beginning of October, and applications should be sent so as to reach the Master of Emmanuel (The Master's Lodge, Emmanuel College, Cambridge) not later than September 18.

The new statute authorising the degree of Doctor of Philosophy for Research has been approved by his Majesty the King in Council, and regulations giving effect to the new statute will be offered for acceptance at the first Congregation in the Easter term.

Mr. F. B. Smith, of Downing College, has been appointed reader in estate management.

Vacancies are announced in the Cayley lectureship in mathematics and in the University lectureships in physiology and zoology. Candidates must apply to the Vice-Chancellor by April 20.

EDINBURGH.—In consequence of the appointment of Mr. W. G. Craib, of the botanical department, to the chair of botany in the University of Aberdeen, it has been arranged as a matter of urgency that Sir George Watt, formerly professor of botany in the University of Calcutta, deliver the course of lectures on Indian forest trees during the summer term.

Mr. James Templeton has been appointed lecturer in botany in succession to Mr. Pealling (resigned), and Dr. Bella D. MacCallum full-time assistant in the same department.

With the assistance of the Scottish Committee of the Royal Aeronautical Society, the services of four lecturers had been obtained to give a series of lectures

on aeronautics in connection with the engineering classes at the Universities of St. Andrews, Glasgow, and Edinburgh. The University Court voted a grant of 50*l.* to defray the cost of the lectures in Edinburgh, and suggested that the lectures should be open to the public.

M. l'Abbé Breuil, of Paris, has been appointed Munro lecturer on prehistoric archæology for the academical year 1920–21.

LIVERPOOL.—The University, through its Chancellor, Lord Derby, has just issued an appeal to its constituency, the counties of Cumberland, Lancashire, Cheshire, and North Wales, for funds that will enable it to come abreast of present needs. Some of the laboratories have been in existence since 1881, and are obviously inadequate, while all of them are now too small; thus the practical course in elementary physics is being repeated eleven times each week. The library needs to be extended; the chemical laboratories are so overcrowded that work is being carried on in Army huts; new departments are contemplated and interesting developments are being thought out. A chair in the mathematical theory of statistics, a ship-model tank, a department of colloidal chemistry, and a department of marine food industry are among the "futurist" ideas that make this appeal so relevant to a great industrial and commercial centre. It is hoped that the sum of a million pounds may be obtained, and of this about 500,000*l.* is urgently required for pressing expansions. Already about 200,000*l.* has been promised.

ON Saturday last, March 20, the third annual dinner of the metallurgy department of the Sir John Cass Technical Institute was held, Mr. G. Patchin, the head of the department, being in the chair. Dr. C. A. Keane, the principal, replying to the toast of the institute, stated that at the present time there are more than a thousand individual students attending the various courses. In 1904 there were three courses and twenty-two students in the metallurgy department, and this year there are eleven courses and one hundred and twenty students.

ONE of the most valuable provisions of the new Army scheme is that which relates to the education of the rank and file. The intention is to provide men in the Army with an educational training equal, or even superior, to what is available in civilian life. Every officer in command of a company will be held responsible for the instruction of his men, not only in drill and discipline, but also in the class-room and workshop, and the result will certainly be increased intelligence and efficiency. For the introduction of this substantial reform Col. Lord Gorell, who since 1918 has been Deputy Director of Staff Duties (Education) at the War Office, Sir Henry Hadow, and Mr. P. A. Barnett are largely responsible, and they are to be congratulated cordially that the scheme of Army certificates of education is to come into operation on July 1, 1921. Four classes of certificates are to be awarded on the results of examination. For the third-class certificate candidates must be able to read intelligently a selected piece of English prose, write a simple letter, work simple sums up to and including vulgar fractions in reference to concrete examples, and answer questions on a course of citizenship and history. The second-class certificate will apparently require a standard of attainment comparable with those of the former Preliminary Local Examinations of Oxford and Cambridge; and the first class, involving English, mathematics, geography and map-reading, and (optional) an ancient or modern language, approximately that of the First School Examination. By taking, in addition, two or three single subjects from different groups, a special certificate may be obtained. Various practical subjects may be taken for the second-class certificate, and the groups for the special certificate include mechanics, chemistry, physics, botany, zoology, geology, physiology, civil, mechanical, and electrical engineering, agricultural chemistry, and commerce. We shall watch with close attention the application and results of this educational scheme.

Societies and Academies.

LONDON.

Royal Society, March 11.—Sir J. J. Thomson, president, in the chair.—W. G. **Duffield,** T. H. **Burnham,** and A. A. **Davis**: The pressure upon the poles of metallic arcs, including alloys and composite arcs. In a previous communication (Phil. Trans., A, ccxx., p. 209, 1919) the authors showed that the poles of a carbon arc behaved as though they repelled one another, and methods were described by which the pressure upon each pole could be measured. Reasons were given for attributing this effect to the reaction consequent upon the emission of electrons from the poles under the influence of thermionic or photo-electric action. The present experiments relate to arcs between iron, copper, and silver terminals, the rate of variation of the pressure with current density being measured for the anodes and cathodes. The pressures were greater than in the carbon arc, that within the copper arc being the largest. Assuming that the pressure is due to the projection of electrons, a comparison between the kinetic energy of the electron and that of the metallic atom at the temperature of the poles showed sufficient agreement to suggest that the electrons before projection were in thermal equilibrium with the metal of the pole. The reactions upon electrodes composed of an alloy of silver and copper were also measured, likewise those within an arc between a silver and a carbon pole. In this case the pressure was determined mainly by the material of the pole under examination. The problem of the mechanism whereby a gas may be heated is briefly discussed. Some account is also given of the variation in the potential difference between the poles when the material of one is altered.—J. H. **Vincent**: Further experiments on the variation of wave-length of the oscillations generated by an ionic valve due to changes in filament current. Eccles and Vincent have found that in an oscillatory circuit maintained by a thermionic valve with a grid coil coupling, the wave-length has a maximum value for a certain filament current. This effect is studied further in this paper. In order to vary the filament current, rheostats were designed and used in which the change of resistance was unaccompanied by any sensible change in the self-induction of the filament circuit. The methods of measuring the change of wave-length due to the variation of filament current were different from that employed by Eccles and Vincent, but it was found that the results obtained were independent of the particular method by which the wave-length was studied. It is suggested that changes in several of the variables of a valve-maintained circuit produce effects of the same sign on the wave-length and the amplitude of the oscillations. The wave-length and amplitude decrease with the decrease of the grid voltage or of the plate voltage. They also decrease when the coupling of the grid coil with the main oscillator coil decreases. Increasing the resistance in either the condenser branch or the induction branch of the main oscillating circuit lessens the amplitude and wave-length; while altering the filament current

in either direction from that giving the maximum wave-length gives also a decreased amplitude.—H. A. **Daynes**: The theory of the katharometer. A historical introductory note by Dr. G. A. Shakespear gives a description of the katharometer and an account of its development by him for hydrogen purity measurements and similar work in connection with lighter-than-air craft. The paper discusses the conditions which determine the temperature of the hot wire in the katharometer cell, and shows that loss of heat by conduction through the gas is the most important factor, convection and radiation being quite unimportant. Equations are given expressing the experimental law of heat loss in a single katharometer wire, and these are applied to the case of two wires in parallel in the arms of a Wheatstone bridge. These equations are then used to show what are the conditions for greatest sensitiveness and precision in various cases arising in practice.—H. A. **Daynes**: The process of diffusion through a rubber membrane. The nature of diffusion of gases through rubber membranes is discussed in the light of some recent work. This all points to a simple process, determined by the case of diffusion through the rubber, and by the absorption of the gas by the rubber. This is introduced mathematically into the problem of diffusion through a membrane. The unsteady state is considered, in which the membrane, after being exposed to air, is suddenly exposed on one side to, say, hydrogen, and the rate of emission of hydrogen from the other side calculated. The passage of gas through the material is treated purely as a diffusion problem, the boundary conditions only being determined by absorption. It is shown that measurements of the permeability of a membrane and of the lag on reaching a steady state are sufficient for the determination of both absorption and diffusion constants. Experiments are described in which these conditions are fulfilled. The measurements of the diffusion are made by means of a katharometer. From these experiments the constants of diffusion and absorption for hydrogen, nitrogen, oxygen, carbon dioxide, nitrous oxide, and ammonia are determined. Temperature coefficients for the constants are given for hydrogen, and the high temperature coefficient of permeability of rubber is shown to be due chiefly to the high temperature coefficient of the diffusion constant. The extraordinarily high permeability of rubber to carbon dioxide, ammonia, etc., is shown to be due entirely to the high absorption. A relation is also suggested between absorption and critical temperature of the gas.

Physical Society, February 27.—Prof. W. H. Bragg, president, in the chair.—T. **Smith**: The balancing of errors. In calculating functions from Taylor expansions or otherwise, the results obtained by summing any finite number of terms will differ to a greater or less extent from the true results. It is shown in the paper that by suitable modifications of the coefficients the results obtained, even when comparatively few terms of the expansion are taken, can be made to approximate very closely to the true results for all values of the variable between selected limits.—Dr. N. W. **MacLachlan**: Notes on the testing of bars of magnet steel. The paper describes the results of experiments with the Ewing double permeameter. It is shown that the assumption underlying the theory of the method, viz. that the end effects are the same with the long and short bars, is not justified, and that the value of H, as found by calculation on this assumption, is in error. The error did not, however, exceed 1 per cent. for any of the bars tested, but the author concludes that the method is inferior as regards accuracy and convenience to the differential-coil method.—G. D. **West**: The forces acting on heated metal-foil surfaces in rarefied gases. The present paper arises out of two previous papers by the author on the pressure of light (Proc. Phys. Soc., xxv., p. 324, 1913, and xxviii., p. 259, 1916), and consists of an experimental investigation of the nature of certain peculiar movements of strips of thin metal foil surrounded by rarefied gases and exposed to radiation. The experiments deal chiefly with phenomena at gas pressures below 1 cm. of mercury, and it is shown that the apparently diverse results obtained can be connected by a theory based on the work of a previous paper (Proc. Phys. Soc., xxxi., p. 278, 1919). The author concludes that at the highest rarefactions the pressures on the strips arise from the fact that, if differences of temperature exist in an enclosure, the pressure of the gas is not uniform, but varies approximately as the square root of the latter's absolute temperature. The simple conditions that exist at low gas pressures are complicated at the higher pressures by gas currents which differ fundamentally from convection currents, but are closely connected with the phenomena of thermal transpiration.

March 12.—Prof. W. H. Bragg, president, in the chair.—F. H. **Newman**: Absorption of gases in the electric discharge tube.—J. S. G. **Thomas**: A directional hot-wire anemometer. The instrument consists of two fine platinum wires mounted close together, and forming two of the arms of a Wheatstone bridge. These are heated by the current in the bridge. When a stream of gas moves in a direction perpendicular to the wires, but parallel to the plane containing them, the leading wire is cooled, while the second wire, being shielded by the first, is not cooled so much, and may actually be heated on account of the air flowing past it being warmed by the first wire. A deflection of the galvanometer is obtained, therefore, which is reversed if the flow of gas is in the reverse direction. The instrument is much more sensitive than the non-directional hot-wire anemometer.

Linnean Society, March 4.—Dr. A. Smith Woodward, president, in the chair.—R. H. **Compton**: A contribution to our knowledge of the botany of New Caledonia. The subject of this communication is the collection made by Mr. Compton in New Caledonia and the Isle of Pines during 1914 with the aid of money grants from the Royal Society, the Percy Sladen Trust, and the Wort's Travelling Fund of Cambridge University. The specimens collected have been presented to the British Museum, and the greater part have been worked out in the department of botany at that institution. Dr. Rendle gave a short account of the position and physical character of the island, and referred to previous work on its flora and its general characters. Important features are the igneous rocks which form a mountain chain of gneiss in the north-east, and the serpentine formation which covers the southern portion and occurs in larger or smaller areas throughout the island. The flora is rich, and the proportion of endemic forms exceptionally high. The main affinities of the flora are with Indo-Malaya and South-East Australia, the former represented chiefly in the forest regions and the latter in the scrub and savannah regions; and a study of it suggests that New Caledonia is a very ancient land mass which has been isolated for a very long period. Dr. Rendle also gave a *résumé* of Mr. Compton's account of the ferns and gymnosperms. The latter are of great interest; they number about twenty-seven, and are all endemic. Mr. Baker referred to a number of interesting specimens among the dicotyledonous flowering plants, which included

many novelties. Miss Lorrain Smith gave an account of the lichens, which include a new genus and a fair proportion of new species. Miss E. M. Wakefield referred to the fungi, the geographical distribution of which showed points of interest; and Miss G. Lister described the small collection of Mycetozoa.

Geological Society, March 10.—Mr. R. D. Oldham, president, in the chair.—Prof. A. H. **Cox** and A. K. **Wells**: The Lower Palæozoic rocks of the Arthog-Dolgelley district (Merionethshire). This paper gives an account of the geology of the country between the Cader Idris range and the Mawddach Estuary. The physiography of the district was described, and a summary of the work of previous investigators given.

MANCHESTER.

Literary and Philosophical Society, February 17.—Sir Henry A Miers, president, in the chair.—Dr. T. Graham **Brown**: The function of the brain. The activity of an animal, as seen by an observer, consists in movements of its limbs, changes of its attitude, changes in its expression, and so on. This activity is usually called "behaviour." In itself the action is a physiological one, and may be analysed and described in terms of physiological mechanism. It is also used as an *index* of the mental processes. The separate movements of the parts of the body are *integrated* by the nervous system in the total behaviour. This integration may occur at different levels in the central nervous system. The great brain must be present if the animal is to exhibit all the finer shades of behaviour which characterise the normal animal. The two general methods of examination were described and illustrated by experimental observations. Brain injuries and their results in men and animals, with consequential paralysis, and the theory of the "cerebral localisation of functions" were discussed.

Literary and Philosophical Society (Chemical Section), February 27.—Mr. R. H. Clayton, chairman, in the chair.—J. **Allan**: Engineering as applied to the buildings and plant in chemical works.

DUBLIN.

Royal Dublin Society, February 24.—Dr. F. Hackett in the chair.—Prof. Wm. **Brown**: Note on the decay of magnetism in bar magnets. Twenty-one bar magnets of different chemical composition were re-tested for magnetic moment per gram after being laid aside for ten years. The most retentive were found to be magnets with about 1 per cent. of C. and those with about 3 per cent. of Cr. The general results show that in ten years the manganese group lost about 25 per cent. of their magnetism, the tungsten group 20 per cent., and the chromium group about 28 per cent.—T. G. **Mason**: The inhibition of invertase in the sap of *Galanthus nivalis*. The inversion of sucrose in the sap extracted from the leaves of *Galanthus nivalis* takes place with extreme slowness, so that at the end of five days, at a temperature of 29° C., it is still incomplete. The delay is observed whether the sap is pressed from untreated leaves or from leaves the cells of which have been rendered permeable by exposure to intense cold or to toluene vapour; but the delay is least marked in the sap extracted by the first method. It is shown that inversion such as occurs is due neither to the acids of the cell-sap nor to the enzymes of organisms external to the cells, and hence the presence of invertase in the sap seems established. Efforts were made to demonstrate the presence of an invertase-inhibitor by dialysis, and by testing the effect of the sap on yeast-invertase, with negative results. Possibly the greater part of the invertase of the sap is thrown down with the colloids coagulated by extraction, especially during exposure to cold or to toluene vapour. The inversion of the sucrose was traced by thermo-electric observations of the depression of freezing point of the sap. These observations usually showed a comparatively rapid inversion during the first few hours, followed by a slight reversal or suspension of the process for the next few hours, and then a steady inversion at a very slow rate. The reversal is remarkable, and may be attributed to a condensation of hexoses to form sucrose or to oxidation of the hexoses.

Type Ammonites. By S. S. Buckman. The Illustrations from Photographs mainly by J. W. Tutcher. Part xxi. Pp. 9-16+14 plates. (London: W. Wesley and Son.)

Diary of Societies.

THURSDAY, MARCH 25.

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 11.—Sir Alfred Yarrow: Notes on our Economic Position as a Shipbuilding Country.—J. Anderson: Further Notes on the Dimensions of Cargo Steamers.—Dr J Bruhn: Freeboard and Strength of Ships.

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 3.—P. R Jackson: The Stabilisation of Ships by means of Gyroscopes.—Prof. K. Suyehiro: Yawing of Ships caused by Oscillation amongst Waves.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Stephen Graham: The Hope for Russia.

ROYAL SOCIETY, at 4.30.—Prof. A. R Forsyth: Note on the Central Differential Equation in the Relativity Theory of Gravitation.—R. D. Oldham: The Frequency of Earthquakes in Italy in the Years 1896 to 1914.—A. F. Dufton: A New Apparatus for Drawing Conic Curves.—Capt. J. W. Bispham: An Experimental Determination of the Distribution of the Partial Correlation Coefficient in Samples of 30.

CHEMICAL SOCIETY (Annual General Meeting), at 5. Sir James J. Dobbie: Presidential Address.

ROYAL COLLEGE OF PHYSICIANS, at 5.—Sir John R. Bradford: The Clinical Experiences of a Physician during the Campaign in France and Flanders, 1914-1919 (Lumleian Lecture)

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Dr. E. Sloan Chesser: Adolescence and the Continuation Schools.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Discussion on:—(*a*) The Electrical Equipment of Artisan Dwellings (with Introductory Paper by L. Milne). (*b*) The Report of the Earthing Sub-Committee of the Wiring Rules Committee of the Institution.

CONCRETE INSTITUTE, at 7.30.—E. L. Hall: Steelwork in the new London County Hall.

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 7.30.—C I R. Campbell and C. H. May: The Effect of Size upon Performance of Rigid Airships.—Prof. E. G. Coker and A. L. Kemball, jun.: The Effects of Holes, Cracks, and other Discontinuities in Ships' Plating.

CHEMICAL SOCIETY (Informal Meeting), at 8.

FRIDAY, MARCH 26.

INSTITUTION OF NAVAL ARCHITECTS (at Royal Society of Arts), at 11.—Eng.-Com. H B. Tostevin: Experience and Practice in Mechanical Reduction Gears in Warships.—J. J. King-Salter. The Balancing of Rotors and Determining the Position and Amount of the Balancing Weights.—Prof. T. H. Havelock: Turbulent Fluid Motion and Skin Friction.

PHYSICAL SOCIETY OF LONDON, at 5.—Prof. A. S. Eddington and Others: Discussion on Einstein's Theory of Relativity.

WIRELESS SOCIETY OF LONDON (at Institution of Civil Engineers), at 6.—Capt. L. A. T. Broadwood: Harmonics in Continuous Wave Transmissions (Illustrated by Lantern Slides and Experiments).

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—P. L. Young and Others: Discussion on Foundry Memories.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—W. A. Tookey: The Future of the Gas Industry.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION (at 11 Chandos Street, W.), at 8.—Dr. G. H. Lock and Others: Discussion on Care of Minor Ailments in School Children.

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section), at 8.30.—Dr. S. Monckton Copeman The Relationship of Smallpox and Alastrim.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir J. J. Thomson: The Scientific Work of the late The Right Hon. Lord Rayleigh.

SATURDAY, MARCH 27.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir J. J. Thomson: Positive Rays.

MONDAY, MARCH 29.

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduate Section), at 8.—W. D. Pile: The Use of Benzol.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—Delissa Joseph: Higher Buildings for London.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Commander D. G. Hogarth: War and Discovery in Arabia.

TUESDAY, MARCH 30.

TECHNICAL INSPECTION ASSOCIATION (at the Royal Society of Arts), at 5.—Annual General Meeting.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Sir Frank Colyer: Exhibition of Skulls of *Macacus rhesus*.—Dr. C. F. Sonntag: Abnormalities of the Abdominal Arteries of a Young Panda.—A. Loveridge: Notes on East African Lizards collected 1915-1919, with Descriptions of a new Genus and Species of Skink, and a new Subspecies of Gecko.—A M. Altson: The Life-history and Habits of Two Parasites of the Blowfly.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Lantern Meeting) at 7.—E. W. H. Piper: Gloucester Cathedral.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—J. W. T. Walsh and Others: Discussion on Motor-car Headlights in relation to Traffic Requirements.

RÖNTGEN SOCIETY (in X-ray and Electrical Departments, St. Bartholomew's Hospital), at 8.15.

THE Bill to prev[illegible] a Special Indus[illegible]e as to the promotion and assistance of special industries has just been introduced into the House of Lords by Lord Balfour of Burleigh, and, as might have been anticipated, met with a somewhat dubious reception from certain noble Lords who, faithful among the faithless, still bow the knee to the old gods of Manchester. *Autres temps, autres mœurs.* We seem to remember a time when the present sponsor of the Bill made the "happy despatch" rather than obey the behest of the chief apostle of Tariff Reform and Imperial Preference to follow the path he is now treading. But we live in changeful times, and events are apt to play havoc with principles. Lord Balfour of Burleigh is not by any means the only citizen who recognises that the altered economic conditions of the Empire and of the world are nowadays inconsistent with the *credenda* of the Cobden School.

It cannot be said, however, of the new departure that the Bill, after all, deals with a measure of any very great magnitude. Even if it becomes law it is not likely to have any immediate or world-wide consequence. As regards dumping, it is primarily aimed, of course, at our late chief adversary. The Germans, no doubt, would dump again if they could, or saw any advantage in so doing. But from all accounts they are not now in a position to consign any class or kind of goods at prices at which goods of the same class or kind are sold by them at home in the ordinary course of business. It is, therefore, in the highest degree unlikely that the Board of Trade would be called upon for many months, or even years, to come to prohibit their importation from Germany under the powers of the Customs Consolidation Act of 1876.

The present political and economic condition of that prostrate nation forbids any hope that she can for a long time yet, if ever, resume her old position as a great trading community. Her proletariat has now tasted power as never before, and conditions of production are altogether changed. It is certain that in the case of some commodities, sugar, for example, there is nothing to dump, and the prospect that there ever will be is very remote. But it must never be forgotten that Germany is not the only nation that might conceivably resort to dumping in the future, and after our bitter experience we cannot afford to let the future take care of itself.

The provisions of the Bill are very elastic, and the Board of Trade is to be entrusted with a fairly wide discretion as regards prohibition of entry. If the imported goods are shown to be necessary in the national interest they may be admitted under such conditions as the Board may order, and any such order must be brought to the notice of both Houses of Parliament. This would not preclude the Board from taking prompt action when necessary; but the Minister would of course be responsible ultimately to Parliament. As an interference with freedom of trade, even the reasonable safeguards involved in this measure will no doubt be fiercely opposed; and it remains to be seen what power the doctrinaires of the old school still retain. The plain man will find it difficult to see the snake in the grass.

The sections of the Bill dealing with the establishment of the Special Industries Council for the promotion and assistance of special industries are, however, of immediate and pressing importance, and it is to be hoped that, whatever may be the fate of the clauses directed to the prevention of dumping, this portion of the measure will not be sacrificed. It is concerned with matters which may be said to have originated out of and in consequence of the war, and to have been forced upon us in great measure by the action of our late enemies. It is notorious that for years prior to the outbreak of war Germany had by divers arts and cunning contrivance sought to hamper and restrain the development of our industries and to thwart the expansion of our commerce. Her methods at times, especially in foreign markets, had violated every principle of fair trading. Her practices were part of her policy of world-wide aggression—*Deutschland über alles*—no matter at what cost or at what sacrifice of commercial rectitude. It was that policy which produced, and probably precipitated, a war which practically every element of German nationality had conspired for a generation past to bring about. It was only on its outbreak that the extent and character of that conspiracy were realised, and that this country fully recognised how it had been tricked, and with what subtlety one after another of the things that count in the struggle which was contemplated had been "cornered" and impropriated. Chagrined as Germany was by our entrance into the war, it was untrue to say, as she alleged, that jealousy of her impending commercial supremacy was at

the bottom of our action. However disquieted and perturbed we might be with Germany's repeated acts of aggression and with the truculence and arrogance of her methods, strained trade relations would never have induced this Empire to draw the sword. That was not the issue which welded the English-speaking world together. But that Germany should have so imagined is intelligible. She had at least good cause for the supposition.

The special industries which the Bill seeks to promote and assist have originated, so far as this country is concerned, in great measure through and by reason of the war. We were compelled to take them up by sheer necessity. Certain of them were among the things of which the Germans had gradually acquired practically complete control for years past. All of them were necessary to our national welfare, and some of them, under the conditions of modern warfare, were essential to our national existence. Our late experience ought surely to have burnt the lesson into the national mind. Never again must we be dependent on outside sources for our medicaments and dyes, certain metals, magnetos, glassware, and optical instruments. These special industries —enumerated in the second schedule to the Bill— were in great measure started during the earlier years of the war. They are defined to be industries supplying commodities which are essential to the national safety, as being absolutely indispensable to important industries carried on in the United Kingdom, and which formerly were entirely or mainly supplied from countries outside these islands. They cannot be said to be firmly established as yet. Some of them, like the manufacture of synthetic dyes, have made extraordinary progress, and their permanence is only a question of time. Others are being developed with more or less rapidity. But every one of them is the subject of continued scientific inquiry and research, and it is the purpose of the projected measure to foster and protect them during this incubatory period.

To this end it is proposed to create a Council of not fewer than five and not more than nine persons of commercial and industrial experience, to be appointed by the President of the Board of Trade. Its duties will be to watch the course of industrial development and, in consultation with the Department of Scientific and Industrial Research and any other Government Department interested in any special industry, to advise the Board as to the promotion and assistance of the special industries named in the schedule to the Bill, and any other industry which, in the opinion of the Council, is a special industry in the sense already defined. It is required to examine any proposals made as to the promotion and assistance, or any suggestions as to the better organisation or development, of any special industry on the application of any Government Department interested, or any firm or person engaged, in any such industry, to advise the Board as to what steps, if any, should be taken by way of assistance to conserve or promote any special industry, and to indicate the terms upon which, in its opinion, such assistance should be given. It is further required to make an annual report to Parliament stating what has been the progress of any special industry to which State assistance has been given, and what recommendations have been made in respect to it. Lastly, any application made to the Board for State assistance by any firm or person engaged in a special industry shall be referred to the Council, together with any information in the possession of the Board as respects that industry, and the Board may require any firm or persons engaged in that industry to furnish any information which the Council may deem necessary under pain of fine or imprisonment.

These, no doubt, are somewhat drastic powers, but, it must be remembered, they are asked for in the interests of national security, and it is unlikely that in operation they will prove to be inconsistent with the proper interests of private trading. As the Council will be associated with the Department of Scientific and Industrial Research, we assume that it will exert a nurturing influence upon scientific work through which industries are created and developed. No one desires to assist an industry which is not itself endeavouring to grow by the use of knowledge, but when this intention is clearly manifested, the State may very well exercise the function of stimulating it or of removing obstacles to expansion. We are faced with the necessity for doing whatever is within our power to promote the establishment of new industries as a means of increased production, not only because

gressive methods, but also to enable us to meet the vast expenditure which the war has entailed. We have regained in a measure the control of raw materials, and for their profitable use science must co-operate with industry, and both must be the objects of the fostering care of the State. The new measure seems to have been conceived in this spirit.

Science and Scholasticism.

Medieval Medicine. By Prof. James J. Walsh (Medical History Manuals.) Pp. xii+221 (London: A. and C. Black, Ltd., 1920.) Price 7s. 6d. net.

PROF. WALSH has written an attractive and most readable account of the course of medieval medicine. He has painted a good, even a speaking, picture, but it is not a likeness which most first-hand investigators of his material will easily recognise, nor is the voice with which it speaks that which is familiar to them. As to his learning and competence for his task, no question can be raised, but the method he elects to adopt is one which has brought much work on the history of science into not unjustified contempt. There are authors, less well equipped than Prof. Walsh, who occupy their time in ransacking the printed masses of ancient literature and abstracting passages which seem to show traces of practices similar to, yet quaintly different from, those of our own time. This of itself, though neither history nor science, is an entertaining and harmless antiquarian diversion. But it is a different matter when such extracts, riven from their context, are gravely pieced together and presented as an account of medieval science to a public necessarily ignorant both of the original material and of the method of research. If an expert, such as Prof. Walsh undoubtedly is, adopts this method, he leaves no alternative but protest to a reviewer with first-hand knowledge.

Prof. Walsh's attitude towards the medieval past may perhaps be illustrated by a single critical sentence: "We have come," he says, "to know more about Aristotle in our own time, and as a consequence have learned to appreciate better medieval respect for him." This, we submit, is not an attitude with which many Aristotelian scholars or many men of science will be found in agreement. It is undoubtedly a fact that at the present time the reputation of Aristotle stands very high indeed as an observer of animal life; but that was *not* the cause of his appreciation in the Middle Ages. In the scholastic centuries his reputation in physical science,—we omit discussion of his position in other departments,—was based chiefly on his view of the form of the universe and of the nature of matter and of man. His first-hand and very valuable observations on the habits, structure, and development of animals were either neglected or they were misunderstood and placed in series with his oracular utterances on the circular motions of the heavenly bodies, the sub-celestial character of comets, the existence of the outer æther and of the *primum mobile,* the intelligences of the stars, and the continuous nature of matter. It was these conceptions that earned for Aristotle his position in medieval science, and on the errors involved in them Prof. Walsh is content to be silent.

Prof. Walsh similarly places in the forefront of his argument that "the most interesting feature of the work of the North Italian surgeons of the later Middle Ages is their discovery and development of two specific advances of our modern surgery . . . union by first intention and anæsthesia." Now, since the days of Hippocrates, and doubtless before, the medical attendant, both for his patients' sake and for his own, has never been reluctant to prescribe narcotic drugs to those in acute pain. The medieval physician was accustomed to use far more drugs than are contained in the modern pharmacopœia, and he included in his long list many sedative and narcotic substances. The very vices of the nations will tell of this, for there was never a time when men did not seek oblivion from care and pain in that form of unconsciousness which is brought by poppy and mandragora and all the drowsy perfumes of the East. Such devices were as freely used by medical men in medieval as in pre-medieval or in post-medieval times; in the nineteenth century they were partly superseded by the advent of chloroform and ether, though many surgeons even yet give a dose of belladonna or opium in addition to the inhaled anæsthetic as a routine in major operations. Prof. Walsh, however, seizes on the practice of narcotisation before operation in medieval times, and, directing attention to a few references to the administration of anodyne drugs by *inhalation,*—a generally unsatisfactory procedure with such substances,—he boldly writes:

"Hugh [of Lucca] seems to have been deeply intent on chemical experiments, and especially anodyne and anæsthetic drugs. . . . A great many of these surgeons of the time seem to have experimented with substances that might produce anæsthesia. . . . With anæsthesia combined with antisepsis, it is easy to understand how well equipped the surgeons of this time were for the development of their speciality."

The facts are that Hugh wrote nothing on surgery, or if he did his work is lost; that the evidence, such as it is, of his use of anæsthetics is at best but second-hand; that among all the tens of thousands of medieval medical MSS.—there are some fifteen thousand in this country alone—perhaps some dozen have a single sentence referring to this process of inhalation; that inhalation is a measure ill-adapted to the drugs said to

have been used; and lastly, that the principal author who mentions it—Guy de Chauliac—gives no indication that it was a method that he either approved or had ever employed.

This is the general character of the book. History written on these lines has ceased to be scientific, and, however attractive, learned, or entertaining, cannot be regarded as a serious attempt to interpret the past in the light of present knowledge. CHARLES SINGER.

Ancient Camps in Gloucestershire.

The Ancient Entrenchments and Camps of Gloucestershire. By Edward J. Burrow. Pp. 176. (Cheltenham and London: Ed. J. Burrow and Co., Ltd., n.d.) Price 21*s.* net.

AN observer who casts his eye over one of the most delightful landscapes in England, the view of the Severn Valley as seen from the escarpment of the Cotswolds, with the Malvern range and the Welsh mountains in the far distance, must have noticed the numerous ancient fortifications which stud the Cotswold glacis. Wave after wave of conquest and armed occupation has broken against this hill rampart. Goidel and Celt, British, Roman, Saxon, Dane, and Norman in succession occupied these uplands, and gradually brought the rich valley lands under the plough. The camps remain as evidence of these struggles in the distant past, down to the time when Cromwell drew his entrenchments on Churchdown Hill at the siege of Gloucester.

We have little trustworthy history beyond Neolithic flint implements and similar remains of the builders of these fortifications, until some of them, like Chipping Norton and Landsdown, near Bath, were occupied by the Romans probably before they reached the stage of constructing fortified cities on the model of the camps of their legionaries, like Glevum (Gloucester) or Corinium (Cirencester). When Christianity replaced paganism, some of these camps, like those at Churchdown and Oldbury, became the sites of Christian churches.

The oldest form of camp seems to have been the hill-fortress, generally consisting of a strong bank and ditch, either cutting off a projecting headland from the downs, or marking off an area with an irregular oval line of entrenchments, the two ends resting on the escarpment of the hill. But the more developed types are infinitely varied, often showing considerable strategical skill in the selection of the site, the alignment of the ramparts, and the provision of a water supply. Others, again, were not designed for permanent occupation, being merely temporary shelters for human beings, cattle, and grain in the event of a sudden raid by the Silures or other formidable tribes of the West Country.

Much information regarding these camps was collected by the late Mr. G. B. Witts in his "Archæological Handbook of Gloucestershire," by the local historians, and in the Proceedings of the local societies. Mr. Burrow, though not a trained antiquary, has done useful work in compiling this monograph. After an introduction dealing briefly with the ethnographical and historical aspects of the question, he describes in alphabetical order more than a hundred encampments, and he is careful to give references to the authorities on which his notices have been based. A distinguishing feature of the book is the series of excellent illustrations from sketches by the author of all the encampments described. The format of the book is creditable to the local printers, and the monograph, as a whole, is a good example of careful field work and artistic taste.

Principles of Glass-making.

Glass Manufacture. By Dr. Walter Rosenhain. Second edition, largely re-written. Pp. xv+258. (London: Constable and Co., Ltd., 1919.) Price 12*s.* 6*d.* net.

THIS volume is very welcome, because there are so few English books on glass-making. It brings the author's 1908 edition up to date. It is easy to read and interesting throughout. The preface states that the book is intended for those who are users of glass, and makes no claim to be an adequate guide or help to glass manufacturers; this makes the book rather a disappointment to a glass-maker, who, from the title, would expect more explicit information.

The author invariably keeps to general principles, and does not give any practical particulars, and in some cases just stops when there is no need to do so. For example, on p. 17 he states that results serve to show that chemical composition has a profound influence on the mechanical strength of glass, and on p. 18 that the modulus of elasticity was largely dependent on the chemical composition of the glass—then why not say in general terms in which direction the mechanical strength and the modulus of elasticity vary with the chemical composition? On p. 36 the pure sands are stated to contain 0·2 to 0·3 per cent. of iron; this is evidently an error, and should read 0·02 to 0·03 per cent.

The chapter on "Raw Materials" is instructive, but the author overlooks the fact that dolomite is by far the cheapest form in which to introduce magnesia into common types of glass. The remarks on dimension and height of tank furnace crowns

on p. 76 are very good, but the statement on p. 81 that from four to eight fillings are commonly given to pots is not a fact in practice. The principles of annealing discussed in the latter half of chap. vii. are most useful, and confirm the conclusions arrived at by Mr. F. W. Twyman in his paper read before the Society of Glass Technology at Sheffield in February, 1917.

Bottle glass, rolled or plate glass, sheet glass, and crown glass are well explained in general principles in chaps. ix., x., and xi. Chap. xii., on "Coloured Glasses," is good on the whole, but the author has entirely missed the real function of arsenic and antimony in glass-making. The important question of optical glass is treated in chaps. xiii. and xiv., and the requirements are very lucidly explained, but only old methods are detailed; modern developments in manufacture in this branch of the industry are not even mentioned.

The book is well indexed, and will be read with much interest by both users and makers of glass.

Physical Chemistry.

(1) *Introduction to Physical Chemistry.* By Prof. James Walker. Eighth edition. Pp. xiii + 433. (London: Macmillan and Co., Ltd., 1919.) Price 16*s.* net.

(2) *Stereochemistry.* By Prof. Alfred W. Stewart. Second edition. (Text-books of Physical Chemistry.) Pp. xvi + 277. (London: Longmans, Green, and Co., 1919.) Price 12*s.* 6*d.* net.

(3) *La Tension de Vapeur des Mélanges de Liquides: L'Azéotropisme.* By Dr. Maurice Lecat. Première partie: *Données expérimentales; Bibliographie.* Pp. xii + 319. (Gand: Anct. Ad. Hoste, S.A.; Bruxelles: Henri Lamertin, 1918.) Price 45 francs.

1) PROF. WALKER'S "Introduction to Physical Chemistry" has, since its first appearance in 1899, been recognised in this country as the standard work for beginners in this branch of science. No great changes from previous editions appear in the present one; the "selected chapter" method of treatment is employed, each branch of the subject being treated from the point of view of showing how physico-chemical principles are applicable to the student's own practical work in inorganic and organic chemistry. Its past success is no doubt due to this and also to the sound and thorough manner in which the explanatory portions are dealt with.

The arrangement of the subject-matter is much the same as in previous editions; two new chapters have, however, been added, one dealing with "Atomic Number," and the other with "Atoms and Electrons." Several of the chapters have been revised, and a number of additions made with the object of bringing the work up to date. Such additions include brief accounts of Ghosh's equation (1918) to account for the abnormality of strong electrolytes and of Dieterici's equation of state, while mention is made of recent work on specific heat at low temperatures and also of the isotopic elements. A useful feature of the book is a list of important references to the appropriate literature at the end of each chapter. This is a book which can be warmly recommended to students of chemistry.

(2) The author states in the preface to the new edition:

"In general I have tried to condense and re-write the material in such a way as to convert what was, perhaps, too much of a reference book into a more readable text-book. At the same time, by the retention of the references given in the previous edition, the volume still maintains its value as a guide to the literature."

"Certain reviewers of the first edition criticised adversely the amount of space devoted to steric hindrance, and in preparing the new edition I have come to the conclusion that they were right, the more so since this subject now attracts less attention than other branches of stereochemistry do. The portion of the volume devoted to steric hindrance has therefore been markedly diminished."

The plan of the first edition has been followed throughout; two new chapters have been added, one being allotted to the Walden inversion, and the other to "The Arrangement of Atoms in Space," a short account of the X-ray work of Profs. W. H. and W. L. Bragg. The book contains three appendices, the first being an interesting account of the relation between physiology and stereochemistry, the second giving directions for making solid models, the employment of which is a great aid to following the subject, and the third containing references to literature on the subject of steric hindrance. The author has succeeded in giving a critical survey of his subject, including recent important work. The book is well got up and illustrated, but contains a few misprints, which, however, are of a minor character.

(3) This book, which was published in Belgium during the German occupation, deals with a very specialised branch of physical chemistry. Azeotropic mixtures are defined as liquid mixtures which, under constant pressure, distil at a constant temperature, their composition corresponding to a maximum or a minimum in the vapour pressure-composition diagram. The work is a

sort of handbook of the subject, and is arranged in three divisions. The first comprises sixty pages, devoted to a theoretical introduction enunciating general laws applying to binary and ternary mixtures. The author gives empirical rules for predicting whether azeotropism will occur in a given binary mixture and for roughly calculating the azeotropic composition and temperature. This portion is concisely written, but rather spoilt by the frequency and length of the footnotes. The second division, which is the largest portion of the book, consists of tables giving experimentally observed data for about 2500 liquid mixtures, mainly binary. As a result of his own experiments, the author points out that azeotropism occurs fairly frequently, some 1000 new binary systems possessing this property having been discovered. In the third division is given a very complete bibliography, and the book concludes with an appendix containing notes on the preparation, in a state of purity, of some of the organic substances employed in the course of the author's researches.

Soils and Manures.

(1) *Soils and Manures in New Zealand.* By L. J. Wild. (New Zealand Practical Handbooks.) Pp. 134. (Auckland, Melbourne, and London: Whitcombe and Tombs, Ltd., 1919.) Price 2s. 6d.

(2) *A Student's Book on Soils and Manures.* By Dr. E. J. Russell. Second edition, revised and enlarged. (The Cambridge Farm Institute Series.) Pp. xii+240. (Cambridge: At the University Press, 1919.) Price 6s. 6d. net.

IT is one of the special charms, as it is also one of the special difficulties, of agriculture to the student that it offers such infinite possibilities of variation in its manifestations of the working of the fundamental laws of Nature, not only from country to country, but also from farm to farm, and even often within the confines of the same field.

How desirable it is, therefore, that the cultivator of the soil shall be doubly armed, on one hand with a sound grasp of the basal principles underlying the relationship of crops to soils, and on the other with a knowledge of the characteristic local environmental factors the resultant effect of which determines the level of crop production attainable on the particular area on which his efforts are concentrated! Yet how can the wonderful complex of chemical, physical, and biological relationships involved in the growth of plants in the soil be so simply resolved that he who ploughs may read! The exposition of scientific principles to the farmer unversed in science, yet engaged in an occupation which represents in its fundamentals perhaps the very acme of complexity in applied science, is a task of the utmost difficulty, and has rarely been accomplished with even moderate success. The common weakness of books of this class, written professedly for the practical farmer, as distinct from the college student, is a failure of the author to keep consistently down to the educational level of his intended reader, to adhere closely to essentials, and to repress the natural inclination to demonstrate his own familiarity with the latest developments of agricultural research, all-important and of absorbing interest to himself, but apt to divert the attention of the reader from the simple essentials which afford him ample material for digestion.

(1) Mr. Wild is fortunate in having in the New Zealand farmer a reader probably on the average better equipped by general education for serious study than the main body of farmers in the home country, and for the particular body of readers to whom he appeals his book is but little open to the foregoing criticisms, so far, at any rate, as the simplicity and clearness of his exposition are concerned. Within the compass of this small book he has condensed a large body of information, much of which will be readily assimilated and found of practical utility by his readers. This applies particularly to his outline of the characteristics and manurial requirements of the various soils of New Zealand. In the exposition of underlying principles to which the first half of the book is devoted, however, we should have ruthlessly eliminated all but the absolute essentials and devoted the space thereby gained to a more leisurely and more fully illustrated discussion of the nature and the mode of action of the latter. Unless we can assume an elementary knowledge of chemistry, physics, and biology in the reader, it is surely better frankly to avoid the attempt at scientific exposition and to concentrate upon implanting firmly in the reader's mind a knowledge of those simple but important conclusions from scientific reasoning and investigation without which he must surely often go astray in his practice.

(2) It is a pleasing indication of the "revival of learning" in British agriculture that a second edition of Dr. Russell's book should have been called for so closely upon its first issue. This work is specifically intended for the young farmer taking a course of instruction of intermediate grade in the type of institution which is now being developed in most counties under the designation of farm institutes. With the teacher's hand to guide him through the more difficult portions, the young

farmer will derive inspiration, together with a useful fund of information, from this book, which is written with the clearness of exposition and forcible reasoning which are so characteristic of all Dr. Russell's writings. The opportunity of a new edition has been taken to embody in the section on fertilisers and manures the new materials and the new points of view which the difficulties of war-time have introduced into British agriculture, whereby the book equips the student with a comprehensive epitome of the resources now at his disposal. C. C.

Our Bookshelf.

Mathematics for Collegiate Students of Agriculture and General Science. By Prof. A. M. Kenyon and Prof. W. V. Lovitt. Revised edition. Pp. vii+337. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1918.) Price 10s. 6d. net.

"THIS book is designed as a text in freshman mathematics for students specialising in agriculture, biology, chemistry, and physics in colleges and technical schools" (p. v). Whatever may be the needs of the American student, the book would scarcely be of use in this country. Originality is not expected in a small book designed to be "the entire mathematical equipment of some students" (p. v), but the chapter on statics would surely be much improved if it contained some account of simple machines. The section headed "Mendel's Law" on p. 282 is defective and misleading; witness the following exercises (p. 284): "A farmer buys two different kinds of thoroughbred chickens, but allows them to mix freely. How many different kinds of chickens will he have at the end of (*a*) the first, (*b*) the second, (*c*) the third year of hatching? *Ans.* (*a*) 3, (*b*) 5, (*c*) 9."

R. A. FISHER.

The Elements of Descriptive Astronomy. By E. O. Tancock. Second edition, revised, with additional matter on practical work for beginners with small instruments. Pp. 158. (Oxford: At the Clarendon Press, 1919.) Price 3s. net.

MR. TANCOCK is the secretary of the committee appointed by the British Astronomical Association for the purpose of encouraging the teaching of astronomy in schools. This book is based on courses of lessons which he gave to junior forms. A large portion of it is descriptive of the aspect and nature of the various orbs, of which excellent photographs and drawings are reproduced. The remainder is devoted to explaining the celestial motions, which is done in a lucid manner. Instructions are given for making a model of the celestial sphere on the surface of a spherical flask that is half filled with some dark fluid. A useful series of questions and exercises is appended, also a set of passages relating to astronomy, selected from English literature, on which explanation or criticism is invited.

An erratum occurs on p. 55. The time of revolution of Saturn's outer ring should be 13·7 hours, not 137.

Vital Statistics: An Introduction to the Science of Demography. By Prof. George Chandler Whipple. Pp. xii+517. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1919.) Price 18s. 6d. net.

THIS manual is intended for American public health officials who, in the author's words, have forgotten most of their arithmetic—not to mention algebra. A good deal of space is consequently devoted to the details of tabulation and the making of diagrams. The census and the statistics of births, marriages, and deaths are fully treated. The absence of uniform laws in the different States of the Union, and the mixed character of the population, are sources of many pitfalls for the student. General rates are of little value in dealing with a population of native-born whites, foreign-born whites, and negroes, and the author duly emphasises the need for care in such cases. The more theoretical parts of the book touch on frequency curves, correlation, and the structure of a life table. In the chapter on correlation, a coefficient 0·54 is described as *low*, and cited as an example of the use of the coefficient as "an admirable weapon for exploding false theories." A public health official would need more technical knowledge than is provided in this book to justify him in rejecting a coefficient of this magnitude.

Insect Life on Sewage Filters. By Dr. W. H. Parkinson and H. D. Bell. Pp. viii+64. (London: Sanitary Publishing Co., Ltd., 1919.) Price 3s. 6d. net.

THE title of this little book is rather misleading. The original matter deals almost entirely with one species of insect, *Achorutes viaticus*, in relation to the efficiency of the sewage filters where it is very frequently found in large numbers. The authors seek to prove that Achorutes attack and consume the colloidal matter and fungoid growths which often choke the upper layers of the filters, and in this way enable a larger volume of sewage to be purified than is possible when these insects are not present. Experiments were made with two filters; in one precautions were taken to exclude Achorutes; in the other the insects were encouraged to develop. Analyses of the effluents produced by these filters showed that where Achorutes was absent the purification effected was less than in the other filter, but when the insects were added to the first filter nitrification improved at once. Although the authors' conclusion seems to be justified, their interesting experiment is scarcely worthy of publication in book form. The biological details appear to be mostly from Haig Johnson's work on the subject.

The Transmutation of Bacteria. By Dr. S. Gurney-Dixon. Pp. xviii+179. (Cambridge: At the University Press, 1919.) Price 10s. net.

THIS small book deals with certain variations, morphological and physiological, which are

encountered amongst pathogenic bacteria. The word "transmutation" is employed by the author to indicate the transformation of members of one recognised species into those of another, and he refers in detail to the arbitrary methods hitherto employed by bacteriologists for the differentiation of bacterial species. Apart from two or three pages in which the author's own experimental work is briefly described, the book is mainly a study of bacteriological literature in the English language. A large part of the abundant publications in foreign languages is either not dealt with at all, or is analysed from English abstracts. There is a good deal of reiteration, certain observations, often obsolete, being utilised again and again in different parts of the book. The use of the apostrophe in "Aertryck's bacillus" seems to indicate that the name is that of a man instead of that of a place. The last chapter, entitled "The Enzyme Theory of Disease," deals with the idea that most of the attributes of pathogenic bacteria can be referred to the activities of ultramicroscopic bodies of the nature of enzymes, and the author considers that this may be the means by which bacteria may exchange many of their characters and functions without themselves undergoing transformation.

The Examination of Materials by X-rays. A General Discussion held by the Faraday Society and the Röntgen Society, Tuesday, April 29, 1919. Pp. 88+64. (Reprinted from the Transactions of the Faraday Society, vol. xv., part 2, 1919.) (London: Faraday Society, 1919.) Price 13*s.* 6*d.*

THE Faraday and Röntgen Societies did good work when they held a joint meeting in April last year and thrashed out the position as regards the achievements, possibilities, and limitations of the method of the examination of materials by X-rays. The present volume will form a most useful jumping-off point for the investigator or manufacturer who desires to know what had been achieved in industrial radiology up to 1919. The contributors to this "symposium number" include many of the leading radiographers in this country who have not confined their interests to medical radiology. Not all the noteworthy work achieved during and since the war was, however, available for publication when the discussion was held.

The first paper, by Prof. W. H. Bragg, forms a delightful introduction to the subsequent papers and discussions, which deal with such varied subjects as steel, light alloys, aircraft timber, carbon electrodes, X-ray plates, etc. There are many excellent reproductions of radiographs.

One realises, from a close reading of the volume, that we stand only on the threshold of radiology, and big and unexpected developments are probable during the next ten years. Both the Röntgen and Faraday Societies are to be congratulated on the results of the meeting. We understand the volume is procurable from the secretary of either society.

Commercial Oils: Vegetable and Animal. With Special Reference to Oriental Oils. By I. F. Laucks. Pp. viii+138. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1919.) Price 6*s.* net.

THIS is a handy little book, intended, not for the oil chemist, but for those persons concerned in the oil industry who have no knowledge of chemistry, or at least no knowledge of it as applied to oils. There are no doubt many such who will often desire to understand what is meant by the various analytical tests and terms used in the specifications on which large users of oil base their contracts of purchase. For example, on p. 70 of the book there is a specification for oil to be employed as a lubricant for aircraft engines; this stipulates that the oil must have (*inter alia*) a certain iodine number, saponification value, flash point, and so on. The author describes in simple terms what these and similar phrases mean, and how they are employed as criteria of the purity and quality of the oil. He gives also short descriptions of the principal oils and fats met with in commerce, and has some very useful advice to offer on methods of taking samples. Even the expert may peruse this part of the volume with advantage, and the non-technical reader should at least have an intelligent idea of the whole subject after studying Mr. Laucks's book.

The Birds of the British Isles and their Eggs. By T. A. Coward. First series. Comprising Families Corvidæ to Sulidæ. Pp. vii+376+159 plates. (London and New York: Frederick Warne and Co., Ltd., 1919.) Price 12*s.* 6*d.* net.

THIS volume of "The Wayside and Woodland Series" of handy pocket-guides affords a popular account of our British birds. Such a work, especially if embellished with good coloured plates of the various species and their eggs, and accompanied by trustworthy letterpress, has long been a desideratum. The figures of the birds are reproductions, much reduced in size, of those in the late Lord Lilford's much-prized book. They are 159 in number, and most of them are decidedly good; but others are disappointing from the fact that the three-colour process has not been equal to doing them justice. The figures of the eggs, which are from one of the editions of Hewitson's well-known book, are disappointing for the same reason, and will mislead the tyro who attempts by their aid to name many of his specimens. There is also an acceptable series of black-and-white illustrations devoted to nests, etc.

Mr. Coward's letterpress, as one would expect, is good, but it is questionable if his excellent descriptions of habits have not been awarded too much space at the expense of other sections, among them the British distribution of the more or less local species. Given a knowledge of the bird and where it is likely to be found, its various activities may be observed by those who care to devote their attention to the delights of bird-watching. This neat and useful little volume—the first of the series on birds—will, no doubt, be

much appreciated by those who desire a popular book at a moderate price.

Practical Exercises on the Weather and Climate of the British Isles and North-west Europe. By W. F. Stacey. Pp. vii+64. (Cambridge: At the University Press, 1919.) Price 2s. 6d. net.

MR. STACEY has produced an excellently planned little book, a model of the way in which a specific inquiry into a subject of relatively narrow compass should be conducted. But, although the methods he adopts are suitable for school work, the subject-matter under consideration is not geography, and is not necessary for all or perhaps for any of the forms of a secondary school. Mr. Stacey has selected a typical set of weather data for the British Isles from the Daily Weather Reports, and has based thereon exercises in which the pupils construct and interpret weather maps. Naturally enough, the work is based upon the records of pressure observations, and his titles include the terms "cyclone," "depression," "wedge," "col," and "anticyclone." The exercises deal with weather records, but not with climate. It is fairly certain that the study of pressure, as distinct from the study of isobars, is out of place in a school geography course unless carefully correlated with a well-developed course in physics, and it is to be feared that Mr. Stacey's efforts will lead to a juggling with words and symbols rather than to a comprehension of atmospheric conditions.

Alternating Current Work. An Outline for Students of Wireless Telegraphy. By A. Shore. Pp. ix+163. (London: Wireless Press, Ltd., 1919.) Price 3s. 6d. net.

As shown by the sub-title, this work is addressed to students of wireless telegraphy. It outlines, without very elaborate mathematics, the general principles of alternating currents and their generation, transformation, etc., in a way readily intelligible to those having already some general knowledge of electricity and magnetism. As the book advances, the treatment specialises more and more in the direction of wireless working. Discussions of the influence of inductance and capacity lead up to a consideration of resonance, and high-frequency resistance is given a prominence justified by its importance in this class of work. A few typical measuring instruments, as used in wireless installations, are briefly described at the end. A reviewer, on turning over the leaves for the first time, might receive a false impression from the presence of an illustration in the chapter on alternating-current generators of an obsolete, although historically interesting, type of machine. This is, however, not unduly enlarged upon in the letterpress. The book is clearly written throughout, and should save those for whom it is intended much trouble and waste of time in picking out the parts of the subject that they require from the many more complete and general works on alternating-current working.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Science and the New Army.

THE leading article on "Science and the New Army" in NATURE of March 18 raises a number of points of fundamental importance with regard to the future relations between science and the Services. The whole subject may conveniently be considered under two heads: (a) The utilisation of the results of scientific research for military purposes; and (b) the direct employment in times of emergency of scientific workers themselves.

With regard to the first, the difficulty has been the lack of real contact. The university worker is necessarily largely withdrawn from the problems of every-day life; and this, not through either mental incapacity or unwillingness on his part, as many people seem to think, but mainly because his time is usually fully occupied with teaching or university routine. Thus he is not, in many cases, even aware of the problems which need solution, and some organisation is required to bring them to him. More, however, than this is wanted if he is to give active help, and attention will have to be carefully given to the following points:—

(1) There is a great disinclination among reputable scientific societies to publish work (even though it may be of considerable practical value) which does not constitute a definite advance in science itself. Now, the solutions of many Service problems are, from the scientific point of view, trivial, though laborious. Nevertheless, it is of great importance that they should be *explicitly* worked out and reach the people interested. On the other hand, technical journals often look askance at what they would probably call "academic" contributions. There is here a gap to be bridged.

(2) Even a scientific worker will expect either remuneration or credit for his work; if the Services expect his collaboration, they must be prepared to pay for it. It has frequently happened that scientific men have given their time and efforts without stint and received little beyond mere thanks (if as much), whilst the credit has been monopolised by some administrative official.

(3) It must also be made clear that scientific workers are not wealthy amateurs, and that the sum (sometimes considerable) necessary to finance preliminary experiments must be provided. Further, the Services must be willing to take the worker into their confidence and to let him observe for himself the actual conditions to which his work will apply. Most Service men cannot even state a problem to a researcher, and are incapable of distinguishing between data which are essential and those which are not. It is entirely useless to expect a scientific man to work in the dark, on second-hand statements from them. For example, one cannot work on submarine detection without submarines at one's disposal. Facilities (which may involve the temporary use of a ship, of aircraft, or of troops) are necessary if results are to be obtained.

In this connection I feel doubtful as to the wisdom of the policy quoted in your leading article from the memorandum of the Secretary of State for W[illegible] separating what is called "pure research" (q[illegible] Does this mean "research in pure science"?)

"applied research," which latter it is proposed to restrict to military institutions. This seems an unfortunate distinction. If a research is initiated in view of a definite application, then that application must never be lost sight of, and the whole should be co-ordinated by the same brains, or else the "pure" and the "applied" researchers will be at cross-purposes. The co-ordination should be done by the research worker himself, not by semi-scientific officials appointed for the purpose.

(4) The creation and development of firms willing to carry out experimental work ought to be encouraged and subsidised. Even during the war, and with the backing of a Government Department, it was often a matter of the very greatest difficulty to get firms not to neglect experimental work in favour of mass production.

(5) It would be well if officials would understand that a scientific man does not work in the same way or under the same conditions as, say, an orderly officer or a clerk, and that he should be given the utmost freedom of movement and of hours; that he should not be continually bothered with reports and returns or unnecessary official correspondence; and that usually he does his real work, not in an office, but in the solitude of his study, and sometimes during wakeful hours in the night. They will also have to realise that research work is individual, and that one cannot hand it over from one person to another every six months, as one does a platoon.

(6) Finally, the Services must be prepared to put up with negative results without making a wry face or putting a black mark against the worker. The trail of science is dotted with the bones of dead theories and the remains of unsuccessful attempts, yet it is largely by means of these that science has been built up.

Coming now to the other side of the question, namely, the employment of scientific workers in the Services in an emergency, this is a problem needing urgent and careful attention. Undoubtedly the treatment of it during the war left much to be desired. The only co-operation which the War Office apparently looked for from the universities, previous to the outbreak of war, was that, through the Officers Training Corps, they should provide a proportion of Reserve officers—chiefly infantry—with a minimum of military training of the normal pre-war type. The idea of using the specialised knowledge of the universities for the technical services of the Navy, Army, and Air Force took shape only very slowly, as the development of the actual fighting made it plain that science would play an increasing, perhaps eventually a predominant, part in modern warfare. By that time much of the promising human material which the universities might have supplied had already been wasted. The main difficulty, however, which was then encountered (and still exists) was that the regular military or naval officer upon whom devolved the choice of persons for appointments of a quasi-scientific nature had not, in general, a suitable education or training for estimating scientific ability. The inevitable result was that large numbers of young men with little or no qualifications got taken on in a hurry at their own valuation, while the best use was not made of such real experts as were available.

I feel that the writer of the article in NATURE has hit the right nail on the head when he says: "Until it is made obligatory for a proportion of them [the General Staff] to have had such a training [in science], the fundamental reform will not have been effected." The same, of course, applies even more strongly to the Air Force and the Navy. In the latter the scientific tradition is much more powerful, and there, on the whole, far better and more intelligent co-operation was obtained. I would suggest, however, that what is most urgently needed for General Staff officers is a course of scientific classification and organisation where they would be taught the real meaning of scientific qualifications and the names of living authorities in various subjects. This would enable the military administrator at least to make an intelligent selection.

I also agree that "it is surely most desirable that, for the future, science should have some scheme of mobilisation ready." What is wanted is a mobilisation register of all scientific workers, carried out under the auspices of a committee on which the various scientific bodies and the universities should be represented. This mobilisation register would indicate, from the scientific side, the age, qualifications, and grade of the worker, the nature of the work which may be expected from him, and the remuneration which he is entitled to expect. The Service authorities could then add medical category, arm or branch of Service to which assigned, rank (if it be desired to give a commission), unit, and place of mobilisation.

So far I have dealt purely with the technical side of the Services; but brains are not unnecessary on the executive side, and the suggested register might well be extended to cover men with high intellectual (not necessarily scientific) qualifications who happened also to have had an adequate amount of military training, so that on the outbreak of war they might be ear-marked for Staff appointments. In 1914 we had a highly trained, if small, General Staff; unfortunately, most of them (to their own great honour, but the nation's loss) rushed to the front line, and a large proportion never returned. Their places and the new vacancies created by the expansion of the Army were necessarily filled in an unsystematic way, as emergency dictated. Many of the junior Staff appointments had to be given to men who had had an inadequate general education and no pre-war military training.

The War Office might well consider the possibility of instituting a General Staff Reserve, largely drawn from among university men. The officers of this Reserve should (by expanding the Officers Training Corps organisation or otherwise) be kept in constant touch with the growth of military thought and practice; they might be called up at fairly frequent intervals for courses, or attachments to Regular units, or manœuvres on a large scale, and they should be adequately remunerated for the time they gave.

L. N. G. FILON.

University of London, University College,
March 20.

I HAVE read the leading article on "Science and the New Army" in NATURE of March 18 with great interest but with mixed feelings. The meaning of the word "research" and the value of the investigator who researches have, in my opinion, never been fully appreciated by the official or military mind.

The attitude of repression and discouragement so general at the beginning of the war was particularly depressing for those of us actually in one of the Services, and therefore not free agents. Towards the end, however, there certainly was a distinct and gratifying change of front—a change which, at any rate in the section I knew best, produced excellent results. Yet, with the best intentions in the world, the authorities in their experimental establishments must needs call into existence a bewildering and unnecessary maze of organisation, or rather over-organisation, in which ten men did badly the work of one, and the few true investigators and designers, for whom presumably all this had been arranged, found

themselves so tied and hobbled as to be practically helpless.

It does not seem feasible, in fact, usefully to organise research on such lines. Research—and design, for that matter—speaking again of the little corner I knew, has been almost invariably the result of the strenuous effort of individuals, and not the fruit of the organisation in which these particular individuals happen to have been embedded at the time. It is not meant to imply that there should be no organisation in Government experimental establishments, but, speaking from experience, I feel most strongly that capable investigators and designers will not produce their best if compelled to work in an atmosphere of over-organisation.

What must surely be a matter for congratulation to the body of scientific workers in the country is the fact, which the article referred to brings out, that the Army (and presumably also the Navy and the Air Force) has learnt its lesson, and hastens to admit that there is something to be gained even in peace from the universities and other scientific and technical institutions. Yet here again one seems to detect—perhaps in pessimism—a touch of misunderstanding. The Government's policy (expressed in the following rather unfortunate words) is "to farm out to civil scientific institutions, such as the universities, the National Physical Laboratory, the Imperial College of Science, etc., all pure research that can be profitably farmed out." The universities will surely be only too willing to give the most sympathetic consideration to a co-operative scheme of this sort, provided that the subject-matter of the researches to be "farmed out" is sufficiently interesting and important.

Presumably the Department of Scientific and Industrial Research will be largely responsible for the allocation of these researches, but if at the same time the smallest step is taken towards "the detection of overlap [in research], where such exists, and its elimination," a feeling the reverse of sympathetic will be set up.

Investigations worthy of the name should surely be carried out in all freedom of both thought and action; even the suspicion of interference would be intolerable. The official interest now taken by the Army in scientific research is a great sign of regeneration—if, indeed, it is more than a surface interest, as we all hope. Let us pray that over-organisation of the Government experimental establishments and unsympathetic treatment of civil scientific institutions will not dwarf the growth of the new scheme.

R. WHIDDINGTON.

The University, Leeds, March 23.

THE leading article in NATURE of March 18 directs timely attention to the need for action by men of science if the lessons of the war are not to be forgotten in the Army of the future.

It was impossible in the war to scrap the old machine; years and experience are essential if a better, new one is to be made. But no memorandum or paper policy, or even consultation with experts, will make a good machine unless the right material is used.

In peace-time the new Army should have technical education (in the broad sense) and scientific research as its two main functions; they are the only sound bases upon which an efficient fighting machine can be built. That appears to be accepted. But these functions can only be performed by an Army with an educated staff, led by scientific men who combine originality with administrative capacity. If the main body of the staff consists of men without the rudiments of a scientific education, who will "administer" the men of science and control the allocation of funds, then there will be a largely unnecessary sacrifice of the Army if a great emergency arises.

With regard to the co-ordination of research, it is true that a good deal of duplication must inevitably occur if the independence essential for great discoveries is to be maintained. But there is much unnecessary waste which can be avoided without real restriction of independence. The direct economy is, however, of minor importance; the greatest advantage comes from forming the habit of consulting the right department or the right expert; and this is as necessary for the man of science as for any other man. The late Lt.-Col. W. Watson, whose untimely death deprived the nation of an expert with an almost unrivalled knowledge of the applications of science in war, once related how a board of chemists spent half a day discussing a meteorological problem which could have been solved in half an hour by a single meteorological expert.

E. GOLD.

March 22.

ALL scientific workers whose research has brought them into contact with military authority during the war must appreciate the leading article on "Science and the New Army" in NATURE of March 18, especially the sentences in which it is urged that "science linked to the Army by fussy research co-ordinators acting under a nescient soldier will not solve the difficulty," and that "science will not occupy its rightful position in the new Army" until the General Staff includes a due proportion of officers who are endowed with a scientific spirit and have received a scientific training. Until then some of the outstanding defects manifested during the war will continue. These defects are:—

(1) *The unthinking application of scientific research.* A good instance of this occurred in the issue of the ridiculously excessive diet (based on research under active marching conditions) to our soldiers in Flanders who were unexercised in the trenches, whilst wholly inadequate rations were being supplied during the period of the soldiers' strenuous training in England.

(2) *The delay in seeking expert advice.* Too often G H Q failed to realise how expert advice could help it, and did not trouble to seek it until too late.

(3) *The choice of expert.* The truly scientific worker rarely asserted himself spontaneously during the war; he waited until his advice was asked. The man who forced himself to the notice of the General Staff as an expert was usually unscientific. Thus G H.Q. was "taken in," and came to rely too often on those whom the scientific world considered as being pretentious in greater or less degree. Their one source of strength was that they were usually "practical" men, whereas the men of science in some cases offered suggestions which could scarcely be carried out during service in the field. But in the long run the Army suffered.

CHARLES S. MYERS.

30 Montagu Square, W.1, March 29.

Knowledge and Power.

THE leading article "Knowledge and Power" in NATURE of March 25 strikes a resonant chord. I am a newcomer into the realms of officialdom, but my experience relates to a Department of State which is of new growth and not yet rooted in tradition. Aeronautics in Britain has had its foundations laid on a scientific basis, and technical staffs have been able to build on trustworthy data. In view of the fact that British aircraft obtained an absolute ascendancy over the craft of any other country, Allied or enemy, and that Britain was the only country with this scientific

foundation, it is not unfair to regard the two facts as being, in some measure, cause and effect.

The scheme which led to the scientific basis was announced in 1909 by the then Prime Minister, and was the result of advice from scientific and technical men, of whom it is sufficient to mention the late Lord Rayleigh as leader. Throughout the vicissitudes of air developments—separate naval and military Forces, Air Board, and Air Ministry—the Advisory Committee for Aeronautics maintained a steady course and steady output of fundamental data. It was, unfortunately, not responsible for the conduct of full-scale research at the Royal Aircraft Factory, and the lack of any definite policy on the part of those in control has led to the reduction of the full-scale experimental side to relative insignificance.

During the war large developments in aviation were called for, and scientific and technical men devoted their efforts to make the best of a very difficult situation. The Technical Department was not attached in an advisory capacity to the Royal Air Force, but was subordinated to the Department of Aircraft Production. As a consequence of this it would appear that the responsible advisers of the Secretary of State too frequently found themselves in the position of children crying for the moon. The effect during the war was minimised by the absence of rigid organisation, and has been fundamentally modified by the recent absorption of the Department of Supply and Research by the Air Ministry, whereby the technical side is directly represented on the Air Council. It can now be pointed out at their inception that certain policies are technically unsound.

The result of relegating the Technical Department to a position of inferiority during the war has been little short of a disaster. Within a few weeks of the armistice both the Controller and Deputy Controller had left; they were followed by the three Assistant Controllers and the great majority of the senior members of the staff. It is true that many had only entered aeronautics in view of the war emergency, but the rapidity with which the offices became vacant was, I think, an indication that the atmosphere was one in which scientific and technical ability could not exist.

The process of attrition is not ended, and the best British business firms are attracting the picked men. Aeronautics, from the business point of view, has been a testing-ground of a man's capacity and adaptability, and as the science and practice of the subject are still young it appears to be better for the individual to abandon his special knowledge and to return to general engineering rather than to remain in a profession which has no openings or prospects for those in it. It is no exaggeration to say that the policy adopted by the State towards scientific and technical knowledge in aeronautics has brought this side of the profession to a condition in which its continued existence is doubtful.

The man of science and the technician, particularly the former, is in large measure himself responsible for this state of affairs. He has been content to recognise the importance of the work he has been doing as justification for acceptance, in spite of a non-commercial salary. The conditions now prevailing have brought home to him the fact that he cannot maintain himself in a reasonable standard of life on this basis. In an age when the value of a man's work is estimated in terms of the money he earns, it is not wise to neglect the criterion applied, although all should help in the search for the sounder basis towards which the industrial world is groping its way. As a scientific man I regret that we are not taking the lead, but are considerable laggards in the search for a just method of payment by results.

March 28 L. BAIRSTOW.

Museums and the State.

IN the recent correspondence on this subject the opinion has been expressed that a lack of co-operation between the various national museums has diminished their efficiency. In this connection it may be useful to recall the report of a Committee upon the Science Museum and the Museum of Geology in Jermyn Street of which the first part was issued in 1911 and the second in 1912; the former was discussed in NATURE at the time (May 4, 1911). This Committee, on which science was strongly represented, was appointed by the President of the Board of Education, and consisted of Sir Hugh Bell, Sir James Dobbie, Sir Archibald Geikie, Sir Richard Glazebrook, Mr. Andrew Laing, the Hon. Sir Schomberg McDonnell, Sir William Ramsay, Prof. W. Ripper, and Sir W. H. White. They were asked to advise as to the educational and other purposes which the collections could best serve in the national interests, the lines on which the collections should be arranged and developed, and as to the new buildings to be erected in order to house and exhibit them suitably.

The report therefore deals with the work and functions of the museums, and does not discuss the form of control most suitable for their administration. Here the Committee makes definite recommendations on many sections of the collections, and wherever these connect with other national institutions it insists upon the importance of co-operation, besides commenting upon any cases where overlapping may possibly occur. Thus there already exists a definite scheme governing the relation of these museums to the Natural History Museum, the Museum at Kew, the Imperial Institute, and the map collection of the Royal Geographical Society; and, but for the war, its results would doubtless by now have been apparent.

In concluding its report the Committee notes with satisfaction the arrangement for providing accommodation for the Museum of Practical Geology at South Kensington contiguous to the Natural History Museum and the Science Museum as contributing materially to that co-operation which it had recommended.

The whole report well repays careful study by all interested in museum organisation. F R.S.

The Magnetic Storm of March 22-23 and Associated Phenomena.

A VIOLENT magnetic storm occurred on March 22–23. It had an S.C. ("sudden commencement") about 9h. 10m. on March 22. This was not outstanding, except that the initial increase in H was immediately followed by a reverse movement, bringing the element below its normal value for the next two hours. The normal value was sensibly exceeded from 12½h. to 14h., and again most of the time from 16½h. to 19h. The maximum occurred just after 17h. In the course of twenty-five minutes, from about 16h. 50m. to 17h. 15m., H rose 280γ and fell 360γ. The trace was off the sheet on the negative side for about six minutes near 1h., eight minutes near 1h. 30m., and thirteen minutes shortly after 4h. It was rising rapidly after each reappearance, so that the range shown on the trace, 810γ, was probably considerably exceeded. The largest movements were from 16½h. to 19h. on March 22, and from 0h. to 6h. on March 23. There was a comparatively quiet interlude from 19½h. to 23h. on March 22. The times of greatest disturbance in declination synchronised fairly with those in H. The extreme westerly position was recorded about 17h. 8m. on March 22, and the extreme easterly position near 1h. 40m. on March 23, when the trace was off the sheet for twelve minutes. There were several exceptionally large rapid move-

ments. In the course of about five minutes from 17h. 8m. to 17h. 13m. there was a swing of 1° 35′ to the east, immediately following a somewhat less rapid swing of 44′ to the west. In the course of about twelve minutes from 1h. 9m. to 1h. 21m. on March 23 there were swings of 76′ to west and 59′ to east, and after a minute's pause the latter swing continued, so that declination at 1h. 28m., when the trace went off the sheet, was 1° 35′ less westerly than it had been nine minutes before. The range actually shown on the sheet, 2° 1′, has seldom been equalled at Kew, and as the trace was off the sheet for twelve minutes it was probably sensibly exceeded.

The vertical force trace was complete, the range of disturbance being about 820γ. The disturbance in that element was fairly normal, the value being enhanced on the afternoon of March 22 from 13h. to 23h., and correspondingly depressed on the morning of March 23 from 0h. 30m. to 7h. The times of maximum and minimum were respectively about 18h. 20m. on March 22 and 4h. 10m. on March 23.

The outstanding features of the disturbance were the size and rapidity of the largest movements, and the separation of two very highly disturbed periods by a comparatively quiet interlude lasting several hours. The disturbance was preceded twenty-seven days before (February 24) by a considerable, but much smaller, disturbance, which was in some respects the antithesis of the later one. It lasted only about ten hours, and the largest movements occurred in the course of the first three hours.

C. Chree.

Kew Observatory.

This storm was one of exceptional violence. It commenced suddenly at 9h. 6m. G.M.T. on March 22. The H.F. magnet experienced a sharp positive movement of 37γ, followed immediately by a decrease in force of 41γ (1γ=10^{-5} C.G.S. unit). Similarly, the D. magnet swung sharply to the west and then to the east, the range being 8′ of arc.

After three oscillations on the negative side of the normal, a steady rise of value commenced in the H.F. magnet at 10h. 36m., which lasted until 19h. 10m., when the spot of light began to fall steadily towards the normal value of the force. The general character of the movement was that of one long wave with oscillations superposed upon it, the storm being most violent between 16h. and 19h. 10m. During this period the spot of light passed beyond the limits of registration in a series of rapid oscillations between 16h. 24m. and 16h. 30m., 16h. 46m. and 17h. 12m., 17h. 54m. and 18h. 14m., 18h. 41m. and 18h. 47m., and 18h. 47m. and 18h. 51m. The oscillations became less violent and rapid after 19h. 37m. At 23h. 5m. the spot of light had fallen to a value close to that of the base line, so that the extreme range in this sweep of the curve was from a value greater than 550γ to 52γ.

At 23h. 16m. a rapid oscillatory recovery and increase of value took place, which attained a maximum of 376γ at 23h. 30m. The spot of light then went off the recording drum on the negative edge, crossing the base line on March 23 at 0h. 24m. During the next four hours it was several times beyond the limits of registration on the negative side in a series of rapid oscillations, in which the greatest range exceeded 260γ.

The extreme range in H.F. during the storm was greater than 700γ. This value may be compared with the range on the quiet days during January and February, which had a mean value of 18γ.

At 4h. 20m. the spot of light returned to a positive value, when a series of very rapid shiverings of the needle took place, similar to those which terminated the violent magnetic storm of August 11–12, 1919. These oscillations had a range of about 130γ, and lasted until 8h. 50m. This may be regarded as the end of the violent storm, though the needle continued to be disturbed moderately until midnight of March 25.

The general character of a sinuous S-like curve is well shown on the trace from the vertical force magnet. It crossed the base line at 0h. 44m. on March 23. There was a very rapid oscillation of the needle at 1h. 0m. The spot of light remained below the base line until 6h. 0m., when it gradually rose, with a shivering movement of small amplitude, to its normal value. On the negative side the spot of light was off the recording drum from 1h. 20m. to 2h. 40m. and from 2h. 40m. to 4h. 0m. The extreme range was greater than 900γ, and the greatest positive value was 642γ.

Corresponding to the gradual increase in force in the H.F. and V.F. elements, the declination magnet gradually swung to the west. The maximum disturbance consisted of some rapid swings of the needle between 16h. 24m. and 18h. 48m. The greatest of these was at 17h. 0m., the range being 90′ of arc.

A very remarkable rapid double swing of the needle occurred on March 23 at 1h. 12m. The range of this oscillation was 130′. This corresponds to rapid oscillations in the force elements. The spot of light was now, on the whole, below the base line until 4h. 0m., when there was a rapid movement east and then west between 4h. 15m. and 5h. 0m., with a range of 120′. A series of shivering oscillatory movements then supervened until the end of the storm. The greatest total range in D. during the storm was 160′.

Judging from the three elements, the general movements both in force and in direction were rising with reference to the base line during the daylight hours and falling during the night hours.

The storm was coincident with the appearance of a very great sun-spot group on the sun's disc which appeared between March 16 and 29, and was passing the central meridian on March 22–23. Its mean heliographic latitude was −6°, and it extended from longitude 114° to longitude 150°. It was the biggest group of sun-spots observed since August, 1917, and its disc area, in units 1/5000th of the visible disc, was 34 on March 22.

It was a revival of a similar extended group of spots of large area observed from January 21 to February 3. At the next rotation, February 17–27, this group appeared as an insignificant small spot and dots amidst extensive faculæ. But the magnetic elements began to be disturbed during this second rotation of the spot-group on February 16–17.

Through the kindness of Lt.-Col. Penny, R.A.M.C., the O.C. Queen Mary's Military Hospital, Whalley, in the immediate neighbourhood of Stonyhurst College, I have received the following account of the aurora borealis observed by him in the early morning of March 23:—

"On going out of doors at about 3.15 a.m. I noticed this display, but I do not know how long it had been visible. It was a clear, starlight night at the time. The aurora was exceedingly fine when I first saw it, the best I have ever seen. It consisted of about eight broad beams of light, most of which, except the extreme west and north ones, extended to within 5°–10° of the zenith. The lights extended over about 90°–100° from approximately north-north-east to west by north.

"The beams became pale and brilliant again several times, besides constant slighter variations in intensity. On two or three occasions, within about twenty minutes, most of the beams, more than three-quarters,

disappeared, leaving one or two longish ones. The colour was mostly white, but sometimes reddish in parts, especially nearly due north.

"A curious feature was an oblique band of light, which came and went across near the summits of the vertical beams. I do not think this was a belt of illuminated cirrus, as its brightness seemed to vary independently of the vertical beams, but it is possible it may have been. The lights had diminished considerably by about 3.45 a.m., but had brightened again, though slightly, when I looked out a few minutes later. I do not know what time the display ended." A. L. CORTIE.

Stonyhurst College Observatory, March 29.

Some Methods of Approximate Integration and of Computing Areas.

THE formulæ which Mr. Percival gives in NATURE for March 18 for approximate integration are well known, but there are one or two points in connection with them which are frequently overlooked, especially by writers of books on mathematics for engineers.

(1) The areas bounded by curves the equations of which are of the form

$$y=a+bx+cx^2+\ .\ .\ .\ +kx^n$$

can be obtained from the values of $2m+1$ equidistant ordinates, not only when $n=2m$, but also when $n=2m+1$. That this is so is seen most easily by taking the origin at the centre of the range of integration and noting that

$$\int_{-h}^{+h} x^{2m+1}dx=0.$$

For example, Simpson's first, or three-ordinate, rule gives the area of the cubic

$$y=a+bx+cx^2+dx^3$$

with perfect accuracy, and for this purpose his second, or four-ordinate, rule is in no way superior.

(2) By a very small change in one of the coefficients Weddle threw the seven-ordinate formula (No. 6 in Mr. Percival's letter) into the very convenient form

$$A=\frac{3h}{10}\left[y_1+y_3+y_5+y_7+5(y_2+y_6)+6y_4\right].$$

The loss of accuracy which the change involves is exceedingly small.

(3) Formulæ based upon the assumption that the boundary curve can be represented by an equation of the form above stated give unsatisfactory results when the actual boundary has tangents at right angles to the x-axis. This is really the reason why none of the results obtained by Mr. Percival in applying his formulæ to the quadrature of a circle possess a higher degree of accuracy than that represented by the admission of errors of the order of 1 per cent.

If we suppose the curve to cut the axis of x at right angles at the origin, it is better to assume that it can be represented by $y=ax^{\frac{1}{2}}+bx$ in the neighbourhood of that point.

If y_1, y_2 be the ordinates at $x=h$, $x=2h$, the area bounded by the curve, the axis of x and the ordinate y_2 is given by

$$A=\frac{4h}{15}\left[4\sqrt{2}y_1+y_2\right].$$

The much higher degree of accuracy resulting from the employment of this formula may be illustrated by applying it to Mr. Percival's example of the quadrant of a circle.

The seven ordinates are:—

$y_0=0$	$y_4=0{\cdot}9428090$
$y_1=0{\cdot}5527708$	$y_5=0{\cdot}9860133$
$y_2=0{\cdot}7453560$	$y_6=1$
$y_3=0{\cdot}8660254$	

Using the above formula to find the area between the ordinates y_0 and y_2, and Simpson's first formula for the part between y_2 and y_6, we obtain the value $0{\cdot}7853871$. The true value is $0{\cdot}7853982$; hence the percentage error is only $0{\cdot}0014$, which compares very favourably with the errors ranging from $0{\cdot}8$ to $1{\cdot}34$ per cent. obtained by using the usual formulæ for the whole range.

Mr. Percival's example clearly shows that when the curve has a tangent at right angles to the axis, no material reduction in error is attained by using formulæ with a larger number of ordinates. The use of Simpson's formula over ordinary ranges and of the formula given above in the neighbourhood of such tangents will prove much less laborious and far more accurate. J. B. DALE.

King's College, Strand, March 22.

IN NATURE of March 18 Mr. A. S. Percival gives an example (the quadrant of a circle) in which Simpson's rule (sometimes called his first rule) is more accurate than the "three-eighths" rule, and he remarks: "This result is curious, and shows that a small arc of a circle approaches more nearly to a small arc of a parabola than to a small arc of any cubic curve." Permit me to point out that this inference is not valid, and is based on the almost universal illusion that Simpson's rule is correct to the second order only, *i.e.* for the parabola

$$y=a+bx+cx^2.$$

It is easy to show by simple integration that Simpson's rule holds to the *third* order, *i.e.* for *all* cubics of the form

$$y=a+bx+cx^2+dx^3,$$

passing through the three chosen points. It is thus precisely accurate, not only for the parabola, but also for a singly *infinite* number of curves passing through the three points, even if an inflexion occurs.

One would therefore expect (which I believe to be the case) that where both rules can be applied (*e.g.* if there are seven ordinates) Simpson's rule would be more accurate than the "three-eighths" rule, which is precisely true only for a single curve passing through four consecutive points.

In some cases, when the gradient is not rapid, Simpson's rule is highly accurate. Dr. Lamb ("Infinitesimal Calculus," p. 278) gives an example in the evalution of π to six decimal places from the equation

$$\int_0^1 \frac{dx}{1+x^2}=\frac{\pi}{4}$$

by taking ten equidistant values for x, but he does not notice the illusion to which I refer. I am surprised that such a simple and easily tested truth should so long have escaped the notice of many expert mathematicians. R. A. P. ROGERS.

Trinity College, Dublin, March 20.

Gravitational Deflection of High-speed Particles.

THE result mentioned by Mr. Leigh Page and verified by Prof. Eddington (NATURE, March 11, p. 37), that the gravitational effect on a particle travelling radially is a repulsion if the speed exceeds $1/\sqrt{3}$ times the light-velocity, is given by Hilbert in the *Göttinger Nachrichten* for 1917. The same paper contains interesting remarks on the path of a particle or light-pulse moving spirally round the gravitation centre.

Hymers College, Hull. H. G. FORDER.

Colouring Matters of Plants.

IN view of the fact that many of Nature's most striking colour effects are produced as the result of harmonious groupings of highly coloured plant life, and that it is to the various plant pigments that these fine tints owe their origin, it is not surprising that chemists have striven, from quite early days of the science, to elucidate the chemical structure of these colouring matters, and botanists to discover their relationship to the vital activities of plant life.

During recent years our knowledge concerning plant pigments has been rapidly and greatly enlarged, and observations have been made that are of great significance to chemist and botanist alike, whilst the horticultural possibilities which they seem to indicate should be of interest to even the most casual lover of Nature's beauties.

When referring to plant colouring matters it must be borne in mind that it is necessary to distinguish between the plastid pigments (chlorophyll, carotin, etc.) and the water-soluble sap-pigments. The present article will deal only with the latter group—sap-pigments—but it must not be imagined that this indicates that progress has not been made in the researches upon plastic pigments; indeed, much knowledge concerning them has resulted from the extended and intricate work of Willstatter and others.

The sap-pigments may be divided into two main classes: (i) Derivatives of flavone or of flavonol—sometimes called anthoxanthines—which are pale yellow or colourless when in faintly acid solution, but bright yellow when dissolved in alkalis; and (ii) the anthocyans, which are red when in acid solution, violet to red-violet when neutral, and of varying tints from dull red, or red-brown, to purple and pure blue when in solution in the form of alkali salts. In both groups the individual pigments differ from each other in the amount of oxygen which they contain in the form of phenolic hydroxyl groups and the arrangement of these groups in the molecule.

We owe most of our knowledge of the distribution in Nature of the yellow sap-pigments—which usually occur in plant life in chemical combination with various sugars—to the work of A. G. Perkin, whilst the actual synthetic production of a number of these colouring matters by Kostanecki has confirmed our ideas concerning their chemical structure. How widely these pigments are distributed in Nature will be gathered from the fact that members of this group have been isolated from the following sources: Heather, wallflower, clover flowers, cotton flowers, delphinium flowers, onion skins, violas, poplar buds, parsley, etc. Although yellow sap-pigments derived from flavone have been isolated from a large number of plants and flowers, it is quite certain that pigments of this group are present in a very much larger number of plants than those from which they have up to the present been isolated.

When we turn to consider the pigments of the anthocyan class—the purples, reds, and blues of plant life—the fact of their extremely wide distribution is obvious to everyone. Their presence in petals or leaves is noticeable even where only a small fraction of 1 per cent. of the pigment exists in the flower. That this is so will be fully realised when the fact is considered that the blue cornflower contains only about 0·75 per cent. of its dry weight of the blue pigment cyanin. In contrast with this is the case which has come to light in recent investigations, where as much as 25 per cent. of the flower's dry weight of a yellow sap-pigment was present in a yellow viola, yet this large quantity was completely masked by a mere fraction of 1 per cent. of a plastid carotin colour that was present in the same flower.

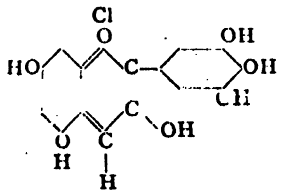
The great beauty of the anthocyan pigments has given rise to very numerous attempts to obtain an accurate knowledge of their chemical structure and also of their function in plant life. The name "anthocyan" dates back to 1835, and appears to have been introduced by Marquart. Despite the very numerous attempts that were made to isolate these pigments in a pure condition, it was not until 1903 that an anthocyan pigment (the colour of the pelargonium) was obtained in a crystalline condition by Griffiths. In 1913 Willstätter and Everest described their investigation of the pigment of the blue cornflower—which they called cyanin—and laid the foundation of the fuller investigation of the anthocyan pigments that has been developed since that date. It is to Willstatter, to his collaborators, and to Everest that we owe most of our knowledge of these pigments. The identity of a considerable number of the anthocyans has now been established, and pigments of this group have been prepared synthetically. Among others, the colouring matters of the cornflower, rose, pelargonium, viola, peony, hollyhock, cherry, and grape have been obtained in a pure condition and investigated. In almost every case these pigments occur in Nature chemically combined with sugars.

As the result of these chemical investigations the relationship that exists between the yellow sap-pigments derived from flavone and the anthocyan colouring matters has been made clear. This relationship has been the subject of much study by botanists, particularly by Keeble, Armstrong and Jones, and Wheldale, and it is interesting to note that, whilst botanical work appeared to point to the anthocyan colours being oxidation products of the yellow sap-pigments of the flavone series, chemical investigations have proved that the relationship is the reverse of this—the anthocyans are reduction products of the yellow sap-pigments.

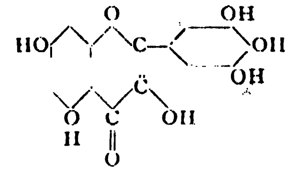
Very interesting in connection with the function of these sap-pigments in plant life is the fact that, whilst chemical investigations have made it clear that the anthocyan pigments are reduction products of the yellow sap-pigments, botanical work strongly points to the conclusion that the very anthocyan pigments occur in plant life in positions that are the seat of oxidising influences.

It has been noticed by many who have investigated the anthocyan pigments that there is always at least a trace of yellow sap-pigment present alongside the red, purple, or blue of the anthocyan. From this has arisen the belief that the anthocyans are produced in Nature *via* the yellow sap-pigments, and recent work has shown that there is very considerable ground for thinking that this belief may prove to be correct.

To even the most uninitiated, the chemical formulæ representing a typical anthocyan [*e.g.* delphinidin (I.)] and the corresponding yellow sap-pigment [myricetin (II.)] make it obvious that a relationship exists between them—



(I.)



(II.)

Naturally, to the horticulturist the interrelationship of the various sap-pigments to one another is of great interest; also the effect of these colours upon the tints produced by the plastid pigments that occur with them in plants and flowers. The proof, by chemical investigation, that the blue cornflower owes its colour to the same pigment as the red rose is of the greatest interest, for does it not raise hopes of success in the endeavour to produce a pure blue rose? In the rose the colour is red because the sap is acid, whereas the cell-sap in the cornflower is in such a condition that the pigment can take up enough alkali to form its blue alkali salt. Can the latter condition be reproduced in the rose?

It is often erroneously stated that the yellow sap-pigments are responsible for the yellow tints in flowers and berries, but in reality the bright yellows are almost exclusively due to plastid colours related to carotin, whilst the orange and brown tints are produced by combinations of these colours with those produced by pigments of the anthocyan group. In some few instances, however, it is probable that sap-pigments give rise to fairly strong yellows, but, in general, members of this class of compound produce pale yellow tints such as the colour of the primrose, or are present in an almost colourless condition in the acid cell-sap of white- or cream-coloured flowers. It is exceedingly difficult, even for one who has studied the pigments minutely, to be certain by mere observation which of the anthocyan pigments is present in any flower that may be examined. Chemical work has shown that plants of the same botanical group may produce different pigments, and, indeed, that more than one anthocyan, or yellow sap-pigment, may be present in the same flower.

Very naturally the clothing of Nature in such beautiful tints, as the result of the presence of these colours, led to the desire on the part of man to use them for the colouring of garments and other textile materials. Many of the members of the yellow sap-pigments are capable of industrial use as mordant dyes, and were largely so used before the synthetic colours became available. Some of them—*e.g.* fustic—are still employed in considerable quantities even in European countries. In the East quite a number remain in use. Concerning the dyeing properties of the anthocyan pigments, much doubt seems to have existed, but it appears certain that in 1850-60 the colour of the hollyhock was largely used in Bavaria for dyeing purposes. Quite recently these colours have been more fully investigated in respect of their dyeing properties, and it has been found not only that they dye wool, but also that they are capable of giving very fine shades when used on cotton with a tanning mordant. Although they have considerable tinctorial power, and the dyeings produced by them are fast to light, they do not stand washing sufficiently to make it possible for them to hold their own against synthetic colours.

Apart from the two main groups of sap-pigments, with which the above remarks have been concerned, there are quite a considerable number of coloured compounds that exist in plants in some soluble form—usually as glucosides. It should be noted that, whilst flavone or flavonol derivatives are very widely distributed, and the anthocyan pigments almost equally so, the remaining colours are much more restricted in their distribution. What *rôle* the flavones, either alone or accompanied by anthocyans, play in plant life, other than that of decoration, has not yet been discovered. Wide distribution is no indication of commercial importance as regards plant colouring matters, and some colours that are by no means widely distributed are of considerable importance. Furthermore, the question of plant colouring matters does not end with the consideration of those colours that exist ready-formed in the plant. Indigo, the most important of all plant colouring matters, exists in plant life as a soluble, colourless glucoside called indican, which produces indigo only when it loses the sugar with which it is chemically combined, and is oxidised by contact with air or other oxidising medium. The archil or cudbear group constitutes another class of colours that were formerly of commercial importance, and are produced from soluble colourless products present in various lichens. In conclusion, the important dye alizarine should not be omitted; this product was formerly obtained exclusively from plant sources—chiefly madder-root, in which it occurs partly as the glucoside ruberythric acid—whereas almost all the alizarine that is now used is prepared synthetically from the coal-tar product anthracene. It would appear that the time is not far distant when all plant pigments that are used for technical purposes will be displaced by synthetic products, but the recent shortage of synthetic dyes has certainly somewhat prolonged the commercial life of the various natural colouring matters.

Geodetic Survey in North America.[1]

THE United States Coast and Geodetic Survey has long had in progress an arc of primary triangulation along the 98th meridian of longitude. This arc was completed to the north, up to the Canadian boundary, in 1907. To the south there is a similar arc along the same meridian through Mexico, originally surveyed by the "Commission Géodésique Mexicaine" between 1906 and 1910, terminating to the north at the international boundary on the Rio Grande and extending southward to the Pacific Ocean.

It was obviously desirable that these two arcs should be connected, and it was accordingly arranged to make the connection in 1913, when the last section of the work in the United States was done. The internal condition of Mexico, however, did not permit any joint operations at that time, and a postponement was necessary. Opportunity was taken of the improved condition of the country in 1915 to revive the question. The arrangements proceeded without hitch and the final observations were successfully made in May, 1916. The publication under review gives an account of the southern end of this arc in Texas, surveyed in 1913, the junction with the Mexican arc in 1916, and a general summary of the progress to date of the lines of first order triangulation in the United States.

Since 1901 the Coast and Geodetic Survey has reduced all its work to a common datum and computed all positions and azimuths upon Clarke's 1866 spheroid. These, both datum and spheroid, have been accepted, on one hand by the Canadian, and on the other by the Mexican, Geodetic Surveys, so that they are now common to the whole of North America. An inspection of the index map of the triangulation lines in the United States computed to these data shows, however, that there is still a considerable block of triangulation in the Eastern States not yet re-adjusted. When this readjustment is made and when certain lines in the Central and Western States, now in progress, have been completed, the network over the whole area will be so close that no point will be situated at a greater distance from a main triangulation line than about 170 miles. In fact, even this distance will be rarely attained, and over almost the whole area the maximum distance will be under 150 miles.

Such a network of absolutely first-class work is amply sufficient to satisfy the most exacting geodesist and is, of course, more than a sufficient basis for any possible map upon any practical scale. We may, therefore, congratulate the U.S. Coast and Geodetic Survey upon the now not distant completion of one of the main sections of its great task.

The execution of the small section of triangulation under review was marked by no special technical advances; but as exhibiting a high level of technical efficiency and as being of possible use for future guidance in similar work that may be planned in British territories, we may briefly advert to one or two practical points. One question of considerable importance is to decide whether it is desirable to restrict observations to the night or whether day observations should be included. The U.S. Survey adopts the principle of allowing only night observations, for the stated reason that experience has shown that there is less deviation in the geodetic azimuths of the lines when this restriction is enforced than when the observing is done by day or is a combination of day and night work. In other words, the atmospheric conditions are more stable at night and observations of angles, therefore, more accurate. This is in accordance with general experience and practice. It has, however, been argued, not without a certain show of plausibility, that though undoubtedly the apparent errors are thus reduced, this may be at the risk of introducing systematic errors, due, let us say, to unsymmetrical atmospheric refraction operating only when observations are made upon a falling temperature, which might be eliminated if observations under different atmospheric conditions were combined. Though plausible, this argument is, we think, not tenable, or, perhaps more correctly, not applicable to the case of a triangulation.

The ultimate test as to whether, in deriving the most probable mean of any set of observations, systematic errors are likely to be diminished by the inclusion of observations of an inferior degree of accuracy but differing in their conditions can be decided only by experience. Now in this case the "experience" is immediately available, being, in fact, implicitly contained in the figure expressing the closing error of the triangle. Any method of observation and any system of combining the results of the observations into a mean value which reduce this closing error *ipso facto* increase the probable accuracy of the finally derived figures of position and azimuth. Night observations, preferably between, say, three hours after sunset and one hour before sunrise, fulfil this condition and are therefore rightly accepted as ideal.

The U.S. Survey, operating over a huge area with a necessarily limited budget, has perforce to pay attention to the question of cost. Survey is, in fact, on exactly the same basis as other engineering operations. The problem is to get the maximum output of work of a strictly defined and practicable degree of precision at the minimum cost, and not, as has sometimes been assumed, to reach the highest attainable precision regardless of cost.

The standard for first order work in the United States is an average triangular error of one second of arc and a maximum error of under three

[1] [illegible] Mexico, and on Triangulation in Southern Texas. By William Bowie. (Special Publication No. 51.) Pp. 93. (Washington: Government Printing Office, 1919.) Price 10 cents.

seconds. This already high degree of precision was, however, surpassed in the particular section under notice. Thus over a total of sixty-eight triangles the average closing error was 0·63″ and the maximum error of any one triangle 1·86″. This pitch of excellence was moreover attained without any increase of time spent at the stations; indeed, it is claimed, we think with justice, that the arc establishes a "record," both technically and financially. The average cost per point occupied was, in fact, lower than has been attained with any previous work of the same class, and as, owing to the nature of the country, high and expensive signal scaffolds were necessary, it seems that the reduction made in the cost of the actual observing was even more notable than appears on first inspection.

This conveys a lesson which may be taken to heart by those responsible for future survey operations. It seems clear that the difference in method of execution between what we are accustomed to call first order or primary triangulation (*i.e.* triangular error under 1″) and secondary work (triangular error under 3″) lies mainly in the nature of the signals. If lamps only are used it is a matter of indifference as regards rate of progress, and hence as regards cost, whether a large instrument capable of first order precision or a smaller one capable only of second order is used. In either case one observer can complete the observations at a station in one night, and no reduction in size of instrument, in number of rounds taken, or in order of accuracy will enable him to do more. The difference in cost of transport between the two instruments is in most cases negligible. The only extra cost involved is that caused by the necessity of providing five lampmen or lamp parties and moving them from point to point. In rough country this might undoubtedly prove a formidable addition, but in the case of future boundary commissions or land surveys in Africa it is anyhow worth serious consideration whether a backbone or net of primary triangulation, planned so as to fit in with a comprehensive geodetic scheme, cannot be undertaken without a prohibitive increase in expenditure.

This is the sort of question for which the co-ordinated experience and authority of a geodetic institute would prove invaluable, and it is to be hoped that it will not be long before such an institution, long overdue, is established in England for the British Empire. E. H. H.

Science and Research in the Air Service.

THE Air Estimates for the year 1920–21, recently presented to Parliament, show a total estimated expenditure of 21 million pounds compared with 54 million pounds in the previous year. The apparent saving in cost is 33 millions, but it is really greater, for in the year 1919–20 the cost of the experimental and research services was borne jointly by the Admiralty and the Ministry of Munitions, and is now wholly included in the Air Ministry vote.

As regards the Royal Air Force, the number of officers, warrant officers, non-commissioned officers, airmen, and boys provided on the establishment (exclusive of those serving in India) has fallen from 150,000 in 1919–20 to rather less than 30,000 in 1920–21—a striking reduction. The 21 million pounds for the new financial year includes rather under a million for civil aviation and two and a half millions for experiment and research. This latter sum would have been more than three millions (3,177,000*l.*) had not an "appropriation in aid," due to the sale of certain airships for 600,000*l.*, come to the relief of the vote. The actual figures are as follows:—

	£
Liquidation of war liabilities ...	1,334,000
Works, buildings, and lands ...	140,000
Aeronautical inspection ...	80,300
Airship constructional establishment	315,000
R.A.E., Farnborough	401,200
Technical equipment and materials	844,390
Salaries and wages	48,800
Miscellaneous	13,850
	3,177,540

An expenditure of more than three millions for research alone in a single year would appear to be a generous provision, but an examination of the foregoing figures shows that much of the expenditure will not be employed for this purpose.

The air vote for meteorological services has risen from 12,000*l.* in 1919–20 to 77,629*l.* in 1920–21, and part of this will doubtless be used in research work of some kind, though these services are not part of the research directorate, but come under the civil aviation side of the Air Ministry. The sum of 77,629*l.* includes the provision of only 358*l.* for "experimental stations," which is such a very modest amount that we assume experimental research in meteorology is provided for by other aid. In any event, the amount cannot represent the degree to which attention is given to research, since in meteorology there is ample scope for original work based upon the observations from what may be termed routine stations.

The printed Estimates convey the intention of the Government to make liberal provision for research in aeronautics, but it is impossible to determine precisely what sum of money is thereby devoted solely to "experiment and research," since such work is sometimes carried on at the ordinary air stations. Moreover, 40,000*l.* for the National Physical Laboratory is not borne on the Air Estimates at all, but on those for the Civil Service. The Estimates do, however, include the sum of 20,340*l.* for research "grants to scientific bodies," and 600,000*l.* as an encouragement to invention.

Obituary.

Mr. Sedley Taylor.

The long life of Mr. Sedley Taylor, who died recently at the age of eighty-five years, nearly all of which were spent in public activities at Cambridge, was in many ways notable. Theology, mathematics, physical science, practical economics, and pre-eminently music, occupied his attention. His withdrawal from active theological pursuits (in 1863 he was ordained to a curacy near Birmingham) was not merely a personal event; it was also linked up with the movement for greater academic freedom at Cambridge. About the same time Henry Sidgwick (1869) and Leslie Stephen (1862) gave up their fellowships. So early as 1862 appeared the first edition of Helmholtz's classical treatise on the sensations of tone. A translation into English, published by A. J. Ellis in 1875, increased its reaction in this country both on the physical theory of sound and on the æsthetic principles of music, which it for the first time brought into detailed, reasoned connection. Its influence was much forwarded by Sedley Taylor's book, "Sound and Music," which appeared in 1873, and was the earliest general exposition in short compass by a writer competent on both sides of the subject. An event which his characteristic energy rendered prominent was his invention of an apparatus which he named the phoneidoscope. It consisted essentially of a resonant cavity, with an aperture over which a soap-film was stretched: when the operator sang to it a note nearly in unison with the cavity, the aerial vibrations revealed themselves visibly in whirling movement of the coloured striations of the liquid film.

In these days perhaps such phenomena, now more fully understood, would be regarded as bearing more closely on the properties of the very remarkable structure exhibited by bubbles, being too complex to reveal direct knowledge of the constitution of sound waves.[1] But Sedley Taylor's enthusiasm was infectious. As a testimony to his zeal in connecting up music with acoustics, and also to the relevant state of things in Cambridge at this period, an extract from Clerk Maxwell's Rede Lecture of 1878 on the telephone (then newly discovered) is worth quoting:—

> Helmholtz, by a series of daring strides, has effected a passage for himself over that untrodden wild between acoustics and music—that Serbonian bog where whole armies of scientific musicians and musical men of science have sunk without filling it up.
>
> We may not be able even yet to plant our feet in his tracks and follow him right across—that would require the seven-league boots of the German Colossus; but to help us in Cambridge we have the Board of Musical Studies vindicating for music its ancient place in a liberal education. On the physical side we have Lord Rayleigh laying our foundation deep and strong in "Theory of Sound." On the æsthetic side we have the University Musical Society doing the practical work, and, in the space between, those conferences of Mr. Sedley Taylor, where the wail of the Siren draws musician and mathematician together down into the depths of their sensational being, and where the gorgeous hues of the Phoneidoscope are seen to seethe and twine and coil like the
>
> "Dragon boughts and elvish emblemings"
>
> on the gates of that city where
>
> "An ye heard a music, like enow
> They are building still, seeing the city is built
> To music, therefore never built at all
> And therefore built for ever."
>
> The special educational value of this combined study of music and acoustics is that, more than almost any other study, it involves a continual appeal to what we must observe for ourselves.
>
> The facts are things which must be felt; they cannot be learned from any description of them.

The economic side of Sedley Taylor's work can be illustrated by a conversation with a younger friend of his who was accustomed to see him in his rooms in Trinity College during his last years of feeble health. The talk turned upon profit-sharing, which was introduced by a question about a French statuette on the mantelpiece. To his surprise the younger man, who had to probe for his information, found that Sedley Taylor had been a pioneer, had even been the inventor of that term, and had written a book on the subject, for which he had been decorated for his services towards industrial co-partnership by the French Government, which was at the time closely interested in such matters.

Sedley Taylor was a pioneer in at least two other directions. One of them was the higher education of women. He promoted the foundation of Girton College, and was afterwards its constant benefactor. Towards the end of his life, in 1911, he received the honour of the freedom of the borough of Cambridge for establishing and endowing the first dental clinic that was founded in England. His musical activities pervaded Cambridge, and are too widespread to be discussed here. His generosity, kindliness, and humour endeared him to a wide circle, and in particular to many generations of musical undergraduates.

CYRIL ROOTHAM.

[1] The writer is indebted to Sir Joseph Larmor for assistance on this subject.

We regret to note that the death of Mr. Anthony George Lyster is announced in *Engineering* for March 19 as having taken place on March 17 at sixty-eight years of age. Mr. Anthony Lyster was the second son of Mr. G. F. Lyster, of Liverpool, and father and son between them were responsible for the greater part of the port developments on the Mersey over a period exceeding fifty years. Mr. Lyster was educated at Harrow, and served his pupilage under his father. After holding the position of assistant engineer to the Mersey Dock Board for some time, during which he was responsible for the

construction of important new works, he succeeded to the position of acting engineer-in-chief, and became engineer-in-chief in 1898. He resigned this post in 1913, and then became a partner in the firm of Sir J. Wolfe Barry and Partners, but remained consulting engineer to the Mersey Dock Board until the time of his death. Mr. Lyster became a member of the Institution of Civil Engineers in 1882, and was president in 1914. He served as a member of the International Technical Commission for the Suez Canal, and was consulted with regard to improvements of the harbours at New York, Bombay, Port Elizabeth, Shanghai, etc. He was also a member of the Admiralty Committee on Naval Works at Doon and Rosyth, and associate professor of engineering at Liverpool University.

By the death of MR. W. A. E. USSHER, which occurred on March 19, many British geologists will lose an old friend who, whether in his usual mood of breezy optimism, or in a rarer phase of boisterous pessimism, was always good company. Mr. Ussher joined the Geological Survey in 1868 and was engaged in the mapping of various parts of England, but his name will always be associated with the Devonian, Carboniferous, and New Red rocks of Devon, Cornwall, and Somerset, where he spent most of his official career. His principal contributions to the literature of these formations appear in the Memoirs of the Geological Survey, in the Journal of the Geological Society, and in the Transactions of the Devonshire Association. In his study of the West Country rocks it was his constant endeavour to secure correlation with their European equivalents, and thus he was brought into close association with many Continental geologists of note. In 1914 he was awarded the Murchison medal of the Geological Society in recognition of his labours. Mr. Ussher retired from the Survey in 1909; unfortunately, ill-health since then kept him in almost complete retirement.

By the comparatively early death of DR. R. C. MACLAURIN on January 15 last, the United States have lost an accomplished and energetic immigrant. Dr. Maclaurin was born at Lindean, Scotland, in 1870, and in 1897 was placed in the first division of the first class of the advanced part of the Mathematical Tripos. It was an unusually good year, the candidates including Grace and Bromwich. Dr. Maclaurin was also equal for the second Smith's prize. After graduating, he at first turned his attention to law, but before very long became professor of mathematics in the University of New Zealand. This post he left in 1907 to occupy the chair of mathematical physics at Columbia, N.Y., and two years later became president of the Massachusetts Institute of Technology. He published one legal treatise, and two on the theory of light; besides this, he contributed various papers to the Philosophical Transactions and other periodicals.

Notes.

A LIST of 5604 promotions in and appointments to the Civil Division of the Order of the British Empire "for services in connection with the war" was published on March 30 as a supplement to the *London Gazette*. We notice the following names of men of science and other workers known in scientific circles:—*Knight Grand Cross (G.B.E.)*: Dr. A. E. Shipley, F.R.S., Vice-Chancellor of Cambridge University. *Knights Commanders (K.B.E.)*: Prof. I. Bayley Balfour, F.R.S., University of Edinburgh; Prof. W. H. Bragg, F.R.S., University College, London; Dr. S. F. Harmer, F.R.S., Director of Natural History Departments, and Keeper of Zoology, British Museum; and Dr. J. E. Petavel, F.R.S., Director of the National Physical Laboratory. *Commanders (C.B.E.)*: Prof. H. L. Callendar, F.R.S., Imperial College of Science, London; Dr. C. C. Carpenter, chairman, South Metropolitan Gas Co.; Mr. F. H. Carr, Chief Chemist, Messrs. Boots Pure Drug Stores; Prof. F. G. Donnan, F.R.S., University College, London; Mr. W. P. Elderton; Mr. A. P. M. Fleming; Prof. P. F. Frankland, F.R.S., University of Birmingham; Dr. F. W. Edridge-Green; Prof. W. A. Herdman, F.R.S., University of Liverpool; Prof. J. C. Irvine, F.R.S., University of St. Andrews; Mr. J. G. Lawn; Prof. T. M. Lowry, F.R.S.; Mr. W. Macnab; Dr. R. A. O'Brien, Director, Wellcome Physiological Research Laboratories; Mr. J. E. Sears, National Physical Laboratory; Mr. F. J. Selby, National Physical Laboratory; Dr. T. E. Stanton, F.R.S., National Physical Laboratory; Mr. G. Stubbs, Government Laboratory; Lieut. J. R. F. Wild, member of Sir E. Shackleton's Antarctic Expedition; and Dr. Dawson Williams, editor, *British Medical Journal*.

THE impending retirement of Sir Napier Shaw, who has been the Director of the Meteorological Office since 1905, and as president of the International Meteorological Committee occupies a unique position, marks an epoch in the history of British meteorology. Trained primarily as a physicist, Sir Napier has been able to approach meteorological problems in a scientific spirit. His academic experience brought him into contact with younger men, and by the encouragement he extended to them he raised the level of his subject. As a consequence, there are at the present moment a greater number of men in the British Empire capable of dealing with intricate meteorological problems than in any other part of the world. A heavy responsibility rests on the authorities on whom the duty of nominating Sir Napier's successor falls. When the Meteorological Office was taken over by the Air Ministry last year the change was looked upon with grave misgivings. The near future will show whether the anxiety then felt regarding the wisdom of a step that was taken against the advice of all competent authorities is to be relieved or intensified. It would be an irretrievable calamity if administrative rather than scientific qualifications were to determine the choice. Unless the whole future of British meteorology is to be

jeopardised, the Director of the Office must be a man of high scientific standing who will maintain the leading place which the Office now takes among the nations of the world. For the credit of the nation and in the interests of science we trust that the new Director will be a worthy successor of the one who has given so much scientific honour to the post.

MR. C. E. GROVES, F.R.S., for some years lecturer in chemistry at Guy's Hospital, consulting chemist to the Conservators of the River Thames, and vice-president of the Chemical Society from 1899-1902, who died on February 1, left estate of the gross value of 33,022*l.*, of which amount 20,000*l.* is left in trust for his five sisters for life, and on the death of the survivor of them 10,000*l.* to the Royal Institution for the Groves Endowment Fund for the promotion of scientific research.

Two scholarships, each of the annual value of 300*l.*, are being offered by the Grocers' Company, the object being the promotion of original research in sanitary science. In addition to the sum named, there will be an allowance to meet the cost of apparatus and other expenses in connection with the work. The scholarships will be tenable for one year, but may be extended for a second or third year under certain conditions. The elections will take place in June next, and applications have to be made, on a special form provided, before May 1 to the Clerk of the Grocers' Company, Grocers' Hall, Princes Street, E.C.2.

IN spite of the fact that no regulations have been issued concerning standard time in Finland, Helsingfors time (1h. 40m. fast on Greenwich time) has been almost generally adopted in the country. The inconvenience of following a time which differs from the international zone system based upon Greenwich time was the principal cause of a proposal, made last autumn by the Geographical Society of Finland, to fix Greenwich time +2h. as the standard time of the Republic. A correspondent, "H. R.," informs us that on March 12 the President arrived at a decision in accordance with this proposal. The new standard time of Finland will be adopted by the railways from May 1, 1921, and the calendars for 1921 will introduce it from the beginning of the year. The question of adopting the twenty-four-hour day is under discussion.

THE Works Council Bill has now passed into law in Germany. It provides for the formation of a works council in every works having at least twenty employees (operatives and office staff). Representation then proceeds *pro rata* up to a works employing any number. All male and female workers from the age of eighteen who are in possession of citizen rights are entitled to vote. Among the various provisions of the Act mention may be made of the obligation of the councils in assisting the management by advice with the view of obtaining the greatest economy in carrying out manufacturing operations. They must also co-operate in the application of new methods and in preventing disputes, and assist in the welfare work, etc. These provisions presuppose considerable technical and industrial knowledge on the part of the members of the council—which, it may be added, must not exceed thirty in any one establishment.

AT the annual general meeting of the Chemical Society, held at Burlington House on March 25, the following were elected officers and council for the ensuing year:—*President:* Sir James J. Dobbie. *Vice-Presidents:* Prof. J. B. Cohen, Prof. F. G. Donnan, Dr. H. J. H. Fenton, Prof. S. Smiles, Prof. J. Walker, and Prof. W. P. Wynne. *Treasurer:* Dr. M. O. Forster. *Secretaries:* Dr. J. C. Philip and Dr. H. R. Le Sueur. *Foreign Secretary:* Dr. A. W. Crossley. *Ordinary Members of Council:* Prof. A. J. Allmand, Dr. E. F. Armstrong, Julian L. Baker, Francis H. Carr, Prof. A. Findlay, Prof. F. E. Francis, J. A. Gardner, Prof. J. C. Irvine, Dr. C. A. Keane, Sir Robert Robertson, Prof. J. M. Thomson, and E. W. Voelcker. It was announced that, the supplementary charter now having been granted, an extraordinary general meeting of the fellows would be held at Burlington House on April 29 at 5 p.m. to consider the alterations in the by-laws proposed by the council.

WE have on several recent occasions referred to the advances which were made during the war in wireless telephony to and from aeroplanes. There is also another important use to which electric waves have been put in connection with aerial navigation, in the wireless direction-finding apparatus, which has likewise been brought to a considerable degree of perfection. An interesting demonstration of both these applications was given under the auspices of the Marconi Co. on a Handley Page machine on March 25, when conversations were held with the Marconi establishment at Chelmsford, and messages were picked up and transmitted to the *Times* office in London. The direction-finding apparatus, which was also demonstrated, is apparently a development of the "wireless compass" used at sea, founded on the radio-goniometer of Bellini and Tosi, in which the angular relation of two coils connected respectively to two independent aerial systems at right angles is varied. By rotating a pointer carrying one of these coils a position is found where the signals received reach a maximum loudness and the direction of the incoming waves is ascertained. By plotting cross-bearings of two stations obtained in this way on a chart, the true position can be found. The Marconi form of the apparatus has a working range of 200 to 300 miles when used in conjunction with low-power coast wireless stations. The converse process was used during the war for finding the position of enemy craft from more than one home station, and it is well known that the Zeppelins used a wireless position-finder ex-

on which this worked is, however, believed to have been somewhat different.

THE report of the Royal Commission on Decimal Coinage has just been issued. The majority report, which represents the views of about two-thirds of the members of the Commission, is not in favour of making any change in the denomination of the currency and money of account in order to place them

on a decimal basis. It maintains that this decision is justified by the following considerations:—(1) In any scheme for reducing the existing system to a decimal basis the pound should be retained. (2) The pound and mil scheme is the only strongly supported scheme which complies with this condition. (3) The advantage to be gained by a change to the pound and mil scheme as regards keeping accounts is in no way commensurate with the loss of the convenience of the existing system for other purposes. (4) Grave difficulties will be created by any alteration of the penny. (5) The scheme cannot be tried as an experiment or on a voluntary basis. There are two minority reports in favour respectively of the decimalisation proposals of Lord Southwark and Lord Leverhulme. The investigation makes it clear that many of the difficulties now regarded as insuperable would disappear if our system of weights and measures were such as to familiarise the general body of the community with decimal calculation. This fact will, no doubt, stimulate the advocates of the metric system to renewed efforts to bring about this useful and necessary reform.

DR. R. C. SMITH states in the *Scientific Monthly* for February that there is in the popular mind a surprisingly large amount of misinformation and misconception concerning many forms of natural history, and this is not confined to exotic, but extends to well-known plants and animals. As instances he quotes the belief that the beaver uses its tail like a trowel; that the porcupine shoots its quills at enemies; that certain squirrels and fish fly; that snakes swallow their young in times of danger; that cats suck the breath of babies, and so on. The prevalence of these beliefs is due largely to the fact that a considerable portion of the people do little or no reading, or it is confined to trashy literature. These misconceptions are due to various causes—to hasty acceptance of the opinions of others, to mistaken observation and misinterpretation of the facts involved, but mostly to the fertility of imagination. All this points to the necessity of serious and efficient Nature-teaching in schools, by the agency of which misinformation about well-known objects of natural history can be corrected.

WE congratulate the Hunterian Museum at Glasgow University on its year's record of steady progress. In the Reports on the Hunterian Collections for the Year 1918–19 just received we note especially the growth of the collections of insects of economic and sanitary importance, through the enthusiastic work of Mr. R. A. Staig. The long list of acquisitions in this department bears witness both to Mr. Staig's energy and to the admirable lines upon which he is developing the collection. The geological collections have received a valuable acquisition through the purchase of the balance of the important Leeds collections of fossil reptiles and fishes from the Oxford Clay. The honorary curator of the coin cabinet reports that the resumption of international communication has been responsible for a considerable increase in the number of requests for casts from workers abroad, and the list of consignments dispatched is eloquent at once of the world-wide fame of this museum and of what the war has meant to research workers at home and abroad.

AMONG early palæolithic flint implements found in the river gravels of the South of England there are certain specimens with the point slightly turned to one side. These are regarded as intermediate between the still older rostro-carinate flints and the ordinary palæoliths by Mr. J. Reid Moir, who describes seven examples in detail and discusses them in a recently published part of the Philosophical Transactions (vol. ccix., B, pp. 329–50, pls. 51–57). According to this explanation, the makers of the rostro-carinate implements eventually began to increase the efficiency of their tools by extending the ridge of the beak progressively further towards the butt end, while they chipped the edges of the great flat face until it also became a longitudinal ridge similarly extended. The rostro-carinate implement, triangular in cross-section, thus passed into the palæolithic implement of the "river-drift type," rhombic in cross-section; the two opposite flat faces of the former having been chipped away, and the two opposed great surfaces of the latter being in planes at right angles to them. As the cross-section of a rostro-carinate resembles that of a dog-fish, while the cross-section of an ordinary palæolith corresponds with that of a plaice, Sir Ray Lankester suggests that the latter should be described as platessiform. Other early palæoliths in which one face is flat may have originated from the rostro-carinate type simply by the extension of the ridge of the beak and the simultaneous thinning of the flint, thus resulting in a skate-like or batiform shape.

IN the *Philippine Journal of Science* (vol. xiv., No. 4) Mr. E. D. Merrill continues his work on new or noteworthy Philippine plants. The present contribution contains descriptions of one hundred new or presumably new species, and eighteen new records for the islands. Of the nine genera which are for the first time recorded as Philippine, two are of special interest from the point of view of geographical distribution. One, Cloezia, a genus of Myrtaceæ, has hitherto been known only from New Caledonia, where it is represented by six species. The discovery of a representative in Mindanao, in forest at an altitude of 1700 metres, adds another genus to the remarkable list of genera that are known only from the Philippines and the islands to the south and south-east of the archipelago. The second, Citriobalus, is a small Australian genus of Pittosporeæ, with one species from Java, the range of which is now extended to Luzon. Another Australian species, *Ipomoea polymorpha*, previously known only from Australia and Formosa, has also been found in Luzon.

ABSTRACTS of scientific papers, when giving full bibliographical details and fully indexed, are evidently of greater utility than mere catalogues. An excellent series of abstracts has for many years been prepared by the Chemical Society, and *Science Abstracts*, issued by the Institution of Electrical Engineers and the Physical Society, is a well-known publication. The abridgments of the Patent Office point to the use of abstracts for purposes of search. Within the last

few years the question of abstracting and cataloguing scientific literature has been much discussed, and has become acute. The Mineralogical Society has, on its own initiative, made a start in this direction, and has recently issued the first number of a series of *Mineralogical Abstracts*. This will give notices of papers and books dealing with purely scientific mineralogy and crystallography, and will also direct attention to matters of mineralogical interest in original papers bearing more on petrology, ore-deposits, and economics. The work of abstracting is being carried on by voluntary helpers, but even with this help it is evident that the cost of printing will be more than a small society can bear. It is hoped, if this venture proves to be of some general use, that it may lead to an increased membership of the society.

MUCH attention has been given in recent years to the question of manufacturing alcohol within the Empire for use as motor spirit. In the current number of the Bulletin of the Imperial Institute the possibility of utilising the mowra flowers of India for the purpose is discussed. These flowers possess thick, juicy petals rich in sugar. They are used by the natives as a foodstuff, and especially for the preparation by fermentation of an alcoholic liquor called daru or mohwa spirit. A single tree will yield as much as 200-300 lb. of flowers in a year. The tree also produces a valuable oil-seed, which is exported in fairly large quantities to Europe. During the war the flowers were used in India for the production of acetone, the yield being said to be ten times as much as that obtained by distilling wood, which is the usual source of this substance. The demand for acetone in India in peace times, however, is not great, and large quantities of the flowers would be available for the manufacture of alcohol, and would appear to be an exceptionally cheap source of this material, as the yield is high compared with that from potatoes and other materials commonly used, about 90 gallons of 95 per cent. alcohol being obtainable from one ton of dried flowers. It has been estimated that in the Hyderabad State alone there are already sufficient mowra-trees for the production of 700,000 gallons of proof spirit per annum, in addition to that necessary for the local liquor requirements.

IN the Weekly Service for February 21, issued by the Ministry of Agriculture and Fisheries, there appears some interesting information on the prospective yields of cereals for the season 1919–20. From this information, obtained from the International Agricultural Institute of Rome, it seems that the world is faced with a considerable reduction in its wheat supply. In Australia the yield of wheat for 1919–20 is estimated at 54·4 per cent. of the previous year's production, and this is only 38·3 per cent. of the average of the five preceding years. Similarly, the estimated wheat yield is much lower than last year's average in the Union of South Africa, the United States of America, Rumania, and Argentina. Before the war the average exports of wheat from Russia and India were together equal to the quantity imported into the United Kingdom from all sources, but it will be some time before India can recover from the famine conditions of 1919, while it is highly probable that Russia will not rank as a wheat-exporting country for the next few years. There is, therefore, a vital need for an increased wheat production in the United Kingdom. Not only for this reason, but also because the scheme is thoroughly sound from the practical point of view, the Ministry advises the sowing of spring wheat, and gives practical advice as to varieties, soils, etc.

THE Journal of the Royal Statistical Society for January contains an interesting summary of the growth of Canada (1867–1917), "Fifty Years of Canadian Progress," by Mr. Ernest H. Godfrey, of the Dominion Bureau of Statistics, Ottawa. While Prince Edward Island and the North-West Territories show an absolute decline in population in the period 1871–1911, the total population was nearly doubled, and that of Manitoba increased from 25,228 to 455,614. More than a third of a million immigrants entered Canada in each of the three years 1912–13–14. The acreage and yield of wheat were more than doubled in the decade 1900–10, those of oats increased by two-thirds, and these rates of development were maintained until 1917. In 1870 Ontario produced 85 per cent. of the wheat, 82 per cent. of the barley, and 52 per cent. of the oats of the Dominion; since 1900 the main farm crops have been obtained further west, Saskatchewan producing in 1917 56 per cent. of the wheat, 28 per cent. of the barley, and 34 per cent. of the oats. While the numbers of sheep have steadily declined (1871–1911), those of horses have doubled and of cattle have increased by 50 per cent. Canadian cheese factories produced annually from 1½ to nearly 2 million cwt. (1893–1917), nearly all of which was exported to the United Kingdom. In 1867 there were 2288 miles of railway line; in 1881, 7331; and in 1917, 38,604. The mineral census of 1911 was of so different a character from those of earlier years that it is not possible to quote details of the progress in mineral wealth. The paper is worthy of close attention by all who are interested in Canada.

GEOGRAPHERS are not likely to overlook the continuous exploration and illustration of Alaska by the officers of the United States Geological Survey, further evidence of which is seen in Bulletins 683 and 687, dated 1918 and 1919 respectively. The former contains a number of new maps, where much still remains a blank, of country stretching in from the coast north and west of the Lower Yukon River. The latter provides excellent photographic views, notably plates v. and vii., of the Kantishna region, north of Mount McKinley, where the only population consists of some forty whites engaged in mining.

IT is a pleasure in these times to handle and read so well printed a report as that which inaugurates the "Scientific Survey of Porto Rico and the Virgin Islands" (vol. i., part 1, issued by the New York Academy of Sciences, 1919). The origin of the survey of this outpost-island of the United States is given by Mr. N. L. Britton, and Mr. C. P. Berkey furnishes an introduction to the general geology. The

rocks of Porto Rico divide themselves into an older series, mainly volcanic, which is regarded as Cretaceous or a little earlier, and a sedimentary Cainozoic group, determined by marine fossils to be of Eocene, Oligocene, and Miocene age, Oligocene beds largely predominating. Though it is not mentioned on the cover of the part, a good map of the island, by Messrs. Reeds and Briesemeister, faces p. 30. The scale is 1 : 950,400, and red contours are sketched at 100 ft., 500 ft., 1000 ft., and 1500 ft. In his detailed account of the geology of the San Juan district Mr. Douglas R. Semmes describes the very interesting and very annoying topography of the Tertiary limestone belt, where "pepinos"—we prefer this term, meaning "cucumbers," to Mr. Berkey's "haystack hills" adopted in the paper—give rise to a remarkably broken country. This topography is due to the irregular falling-in of waterways in the Cainozoic limestone, complicated by the occurrence of beds of shale. In the petrographic section we welcome the appearance of Vogelsang's term "vitrophyre"; but the German spelling that is retained, even in a plural, which is written "vitrophyrs," makes us fear that this useful word is here limited as Rosenbusch desired.

AERIAL navigation has become of such vast importance that any aid which meteorology can afford is welcomed, while, on the other hand, the meteorologist looks with much expectation to the airman for observations which may advance our knowledge of the general movements of the atmosphere. The Meteorological Office has just issued "An Analysis of Cloud Distribution at Aberdeen during the Years 1916–18" (Professional Notes No. 9, price 4*d.* net). The analysis is by Mr. G. A. Clarke, assistant at Aberdeen Observatory. It is practically a first effort at averaging the number of days in each month on which certain cloud characteristics are predominant, and from this deducing by the estimated average height of the cloud the occasions when air was cloud-free below certain heights. The number of occasions upon which flying would have been handicapped on account of the lowness of the cloud is 31 per cent. of the total, and of the remainder rather more than one-third show no cloud below 7000 ft. The weakness of the analysis is that the cloud-heights have been worked on average results deduced from altogether different observations. It is recognised by meteorologists not only that the heights of clouds may vary at different stations, but also that they are subject to diurnal and seasonal variations.

IN a paper on operating a by-product producer-gas plant for power and heating, read recently at the Institution of Electrical Engineers, Mr. W. H. Patchell gives particulars of the running of a plant belonging to the Hoffmann Manufacturing Co., Ltd. The gas plant is on the Lymn system, and the power units consist of four-cylinder horizontal Premier engines of about 500 brake-horse-power at 190 revs. per min. Each gas engine is fitted with an exhaust boiler, and the boilers were installed with water-heaters. The dynamos were supplied by Messrs. Crompton, and are open type direct-current shunt-wound interpole 360-kw. machines running at 190 revs. per min.; the first two machines work at 110 volts, and in the second instalment of plant, machines working at 220 volts are used. The figures obtained for a period of six months' running show a consumption of 1·51 lb. of coal per kw.-hour, and a thermal efficiency of 19·9 per cent. on the units delivered to the feeders. The best figure quoted by Mr. David Wilson (Technical Adviser to the Controller of Coal Mines) for electric power stations in the South of England is a consumption of 2·32 lb. of coal per unit and a thermal efficiency of 13·05 per cent. The best station in the Northumberland district gave 1·80 lb. of coal per unit and a thermal efficiency of 18 per cent. Mr. Patchell considers that the large-cylinder high-power gas engine will be developed in this country as it has been abroad—an opinion in which he appears to differ from some other gas-engine authorities.

A PAPER read to the North-East Coast Institution of Engineers and Shipbuilders on March 19 by Dr. W. H. Hatfield, of the Brown-Firth Laboratories, and Mr. H. M. Duncan, of Messrs. C. A. Parsons and Co.'s Research Laboratory, deals with the mechanical properties of turbine steels. Unfortunately, the authors were unable to obtain specimens of turbine steel which had done good service in severely stressed parts, and a standard with which they could compare other steels was therefore lacking, but the conclusion is reached that design has probably more to do with the life of turbine parts than the quality of the steel. One disc which failed in practice, however, proved to be weak when tested in a radial direction, and the defects of structure are illustrated by means of photomicrographs. The paper contains a number of tests by different methods, the conclusions as to the relative value of impact, bending, hardness, and tensile tests being, in the main, the same as those reached by Dr. Hatfield in his paper read before the Institution of Mechanical Engineers. An investigation of the Sankey test is included, the relation between the length, diameter, and resistance of the test piece being examined. A formula is given which yields a rough approximation to the values which would be obtained under standard conditions. Formulæ are also given for the Stanton repeated impact test, and the data collected should be of interest to engineers who are concerned with testing.

SOME interesting particulars regarding the use of mechanical reduction gears between the turbines and the propeller in the Royal Navy were given in a paper read at the recent meeting of the Institution of Naval Architects by Eng.-Comdr. H. B. Tostevin. By 1916 it was considered that enough progress had been made to warrant a complete change-over to this type of driving, and at present there are installed or on order 612 sets of gears of a total horse-power of 7,828,000. The largest set transmits 36,000 shaft-horse-power, and there are four sets on this ship, totalling 144,000 h.p. In all naval work the turbine spindles, pinions, and gear-wheels are supported on rigid bearings, and the alignment is determined by accurate machine work in boring the gear housings and fitting the bearings. In general, a gearing ratio

of 8 or 9 to 1 is not exceeded in naval practice of moderate and high power. Of the 556 sets in service, some extending up to nearly six years, it has only been necessary to remove three for refit due to misalignment; no actual breakdown occurred, and the gears, after dressing up, were afterwards re-utilised. Two cases of fractured teeth occurred; the broken or cracked portions were removed and the damaged teeth were smoothed up. There is a great saving in the blading of the turbine by the adoption of mechanical gearing, amounting in the case of a destroyer to 70,000 ft. of blading in a direct drive, against 7720 ft. in the geared drive. The increase in efficiency is 16·1, 17, and 20 per cent. respectively for light cruisers, flotilla leaders, and torpedo-boat destroyers at full power; at one-fifth power the increases in efficiency are 16·5, 20, and 20 per cent. respectively.

MESSRS. THOMAS MURBY AND CO. are publishing shortly two books likely to interest geological readers, viz. "An Introduction to Palæontology," by Dr. A. Morley Davies, and "Petrographic Methods and Calculations," by Dr. A. Holmes. In the first-named work the "type-system" of Huxley is applied. A limited number of fossil species are described in detail, the relation of the structure to the animal's mode of life being pointed out, as well as the effects of fossilisation. Each such description is followed by a general account of the group of which the "type" is representative. The volume will contain appendices dealing with rules of nomenclature and methods of extracting and preserving fossils. In Dr. Holmes's volume the following subjects receive attention: Specific gravity and porosity of rocks—examination of crushed rocks and loose sediments—mineral analyses by heavy liquid, magnetic, and electrostatic methods—mechanical analysis of sands—preparation of thin sections and their examination by staining, micro-chemical, and other methods—chemical analyses of rocks and their interpretation—representation of analyses by diagrams—suggestions for the description of rocks.

MESSRS. W. HEFFER AND SONS, LTD., Cambridge, have just circulated a miscellaneous catalogue (No. 186) of secondhand books which will doubtless be of service to many readers of NATURE. The more strictly scientific portion contains 100 items ranging over most of the branches of scientific knowledge; a lengthier section gives particulars of works on folklore, mythology, psychical research, comparative religions, etc. The Sanskrit collection of the late Dr. A. F. R. Hoernle, comprising about 400 volumes, is also listed. The catalogue may be had upon application.

READERS of NATURE interested in biography and desirous of obtaining books relating to this subject at small cost should obtain a copy of Catalogue No. 400 just issued by Mr. F. Edwards, 83 High Street, Marylebone, W.1. The list is not particularly strong in science, but it contains lives of Charles Darwin, Sir Joseph Banks, J. J. Audubon, Thomas Bewick, Sir Colin Scott-Moncrieff, and others. There is also a section of works on genealogy and family history. The catalogue will be sent on request.

Our Astronomical Column.

APRIL METEORS.—Of April generally and its special meteoric display it can scarcely be said that they often possess features of striking interest from a spectator's point of view. The fact is that the spring months are usually all deficient in abnormal phenomena of this kind, and observers are sometimes sadly disappointed with the result of their observations; for if meteors from Lyra are absent or few, there is little else to engage the student, as meteors may fall not more abundantly than three or four in an hour.

There are periodic returns of grandeur attached to the Lyrids, but the uncertainty of the periodic time renders it a non-predictive feature. Hence the observer must needs take up his stand with a very doubtful prospect before him.

But the stream of Lyrid meteors has important historical associations, and the shower can boast of a known cometary parentage. These facts, combined with the possibility of a bright and abundant display in any year, lure observers to look for it with an interest and anticipation sometimes amply justified.

SPECTRUM OF η ARGÛS.—As Mr. Baxandall and Miss Cannon suspected changes in the spectrum of this interesting star, Dr. Joseph Lunt took two photographs in February and April, 1919. Each was exposed on three nights with a total exposure of nine hours. The spectrum consists mainly of bright lines; there are dark lines, but they cannot be identified with known lines, and may be merely interspaces between bright bands. The results for radial motion differ according to the lines employed. The enhanced iron lines give −30·7 and −28·2 km./sec. from the two plates. The chromium lines are in fair agreement with this, but the hydrogen bright lines give +46·5 and +48·7 km./sec., a difference of 77 km./sec. from the other lines. On the other hand, hydrogen dark lines give −19 excluding H_β, or −33 including it.

Dr. Lunt suggests in explanation the settling down of an extensive outer hydrogen atmosphere on to the central body. He refers to Mr. Innes's discovery of a faint companion, and notes that hitherto no certain sign of variable radial velocity has been detected. He emphasises the importance of keeping the star under constant watch, both visual and spectroscopic, as the light curve gives expectation of another brightening about the present time. The star is a curious link between novæ and variables, Miss Cannon noting a strong resemblance between its bright-line spectrum and that of Nova Aurigæ on 1892 February 17 (Monthly Notices, vol. lxxix.).

INFRA-RED SPECTRA OF NEBULÆ.—Investigations are being carried out at the Lick Observatory by Dr. K. Burns with the object of securing photographic plates of great sensitivity to infra-red radiations, and some plates prepared by him have been utilised by Mr. W. H. Wright for exploring the spectra of nebulæ in this region. In the Publications of the Astronomical Society of the Pacific, No. 185, Mr. Wright gives an account of his preliminary attempts in this direction, with the results obtained in the case of the planetary nebula N.G.C. 7027. The 36-in. refractor of the Lick Observatory was used with a single-prism spectrograph giving the rather small dispersion of 1 mm. to about 600 A.U. on the plate. The focus was not good in the region required, but fair definition was obtained between λ 6700 and λ 8500, and his photographs show four lines in the extreme red not previously reported. The corrected wave-lengths are given as approximately 7009, 7065, 7138, and 7325, and in addition to these lines there are others at λ 6678 and λ 6730 which have been measured previously with other apparatus.

Hydrographical Studies.[1]

HYDROGRAPHY is a backward science, and the very ocean, scientifically speaking, is a neglected field. Mr. J. Y. Buchanan, an oceanographer himself, tells us so in his new book of "Accounts Rendered":—"It seems almost incredible that the men of all nations, burning with scientific and exploring zeal, should have entirely overlooked, and apparently despised, this large portion of the world." Our *Challenger* Expedition had two faults: it cost a great deal of money, and it was done too well. It has led two generations of Englishmen to believe that the thing was done and need not be repeated, and must on no account be asked for again. Yet, in spite of this great old expedition of ours, and the various scientific exploring voyages of the *Travailleur*, the *Gauss*, the *Siboga*, the *Albatross*, the *Thor*, and all the rest which have followed it (in other hands than ours), we know perfectly well that our knowledge of the ocean, both physical and biological, is in its merest infancy. Its fauna we know as we knew that of the shore fifty years ago, a handful here, a handful there; of its physical and physico-chemical phenomena we know a great deal less.

Nor is this true only of the wide oceans. Twenty years ago we knew, to all intents and purposes, absolutely nothing of the hydrography of the North Sea itself with the one exception of its tides. Its temperatures and densities had never been mapped, their seasonal fluctuations (save at a few shore-stations) were unknown. Even in regard to the tides, and in spite of the great men who have devoted themselves to this favourite subject, we know that we have still a vast deal to learn in theory, and that in practice our tide-tables fall short of the accuracy which modern conditions demand. Things are beginning to mend. The University of Liverpool has established, not only a chair of oceanography, but also a special institute for the study of the tides; and, under the stimulus of international co-operation, a certain aspect of hydrography has come to be an intrinsic part of the scientific work of our fishery departments.

All this is to the good, though not yet nearly enough. The fishery departments are working on imperfect material, with inadequate staffs and still more inadequate laboratories; but better days are coming. Even in these hard times the work will go on, and under much better conditions than before, but we shall scarcely be satisfied! For the physical study of the sea is a very great thing indeed. Of its problems many are scarcely formulated, many others doubtless are still unforeseen. There is no end to them; they range, let us say, from the study of the tides to that of hydroxyl-ion concentrations, from the movements of the great ocean currents to the coefficients of absorption of the sun's rays in the surface-waters of the sea—nay more, they may involve the most fundamental questions of chemical physiology, in relation to the life and the nutrition of one grade of organisms after another. They call, or ought to call, for the widest physical and chemical knowledge and high mathematical skill. Not only must the officials of a department do their daily task, but still wiser and more learned heads must play their part.

There is not one of these problems which has not its practical side—its influence, direct or indirect, on the lives of fish and the lives of men. But the practical outcome of our knowledge lies, for the most part, a good long way off. The tanner, the dyer, or the brewer, the maker of soap or of glass, even the farmer and the gold-digger, come straight to the chemist with their troubles, for they have learned at last that it is worth their while; yet even now when they do so, as often as not the questions they put only suggest a new line of investigation, instead of finding an answer to hand. And chemistry is all but the oldest of the sciences, while hydrography is a thing of yesterday—or rather of to-morrow.

But I have left myself no room, after all, to discuss as they deserve those of Dr. Jee's papers published by the Department of Agriculture and Fisheries. They form a diligent and meritorious contribution to the necessary statistics of hydrography. They set forth fully and clearly (1) the variations of temperature and of salinity during a considerable number of years at the Seven Stones Lighthouse, a station of very obvious importance in the neighbourhood of the Scilly Isles; (2) the same phenomena on a cross-section of the English Channel, from the Isle of Wight to St. Malo; and (3) the same again for the surface-waters of the North Atlantic, in a particular area where warm currents appear to branch off for the ultimate supply of the southern and the northern portions of the North Sea. The data, which are very numerous, are furnished by captains of ships and the keepers of the lighthouse; and Dr. Jee's business has been to reduce to order, to analyse, and, above all, to discuss this large mass of observations. The phenomena so elucidated, and the deductions drawn from them, are too numerous to be discussed here.

On one curious point, and one only, we may say a word. Dr. Jee pays a good deal of attention to a favourite theory of certain meteorologists (Dr. Otto Pettersson among them) that there is a marked alternation of temperatures between the "odd" and the "even" years; that there is at least a *tendency* for the years of even number to be warmer than the odd. Dr. Jee finds considerable support for this theory in the surface-waters of the sea, but subject to curious limitations. He tells us that "it is a fact of undoubted significance that, for a very wide stretch of the Atlantic extending from the coast of Cornwall at least as far as 35° W., the November means are in the aggregate of substantially higher value in the years of even number, and that this value culminates in the area of maximal temperature. . . . This periodicity is a general feature of the waters of the Atlantic east of 35° W., and the persistence of its occurrence is amply demonstrated by the zonal means, which *regularly alternate* high in the November of an even year and low in the year following."

There is here, in short, some definite evidence adduced bearing on the important question of a regular two-year "pulse" of the Gulf Stream. But during other parts of the year exceptions become perplexingly numerous, and Dr. Jee himself tells us that "examination of the monthly means . . . shows that only in November do they exhibit any appreciable conformability to the odd and even rule." Even if the phenomenon were only clearly manifested in November (in this particular region), it might still be of great importance, and we should like to know a great deal more about it. The fact that we are left without a firm hold of the thing is not Dr. Jee's fault at all, but depends on the fact that he is still only able to deal in detail with a particular and limited area. A similarly detailed account of the surrounding areas would soon, I imagine, convince us whether we were dealing with a real phenomenon or not, and if it confirmed would begin to help to explain it.

Public Health and Welfare.

THE forty-eighth Annual Report of the Local Government Board, containing the report of the Medical Department for 1918–19, is noteworthy in many respects. It is the last of what may justly be called a famous series; it is addressed, not, like its predecessors, to the President of the Board, but to the Minister of Health, and its introduction is written by the First Medical Officer of the Ministry of Health. Its contents are noteworthy too, dealing with matters that no one probably even ten years ago would have dreamed of seeing referred to in the Board's report, and with subjects that the early Medical Officers of the Board never thought of in relation to the work of the Board.

The introduction, written by Sir George Newman, takes the form of an interesting little historical note on the origin and growth of the Medical Department of the Local Government Board. To Sir John Simon, who was the first Medical Officer, to Dr. Seaton, who succeeded him, to Sir George Buchanan, to Sir Richard Thorne Thorne, to Sir William Power, and to Sir Arthur Newsholme, the last of the famous line, he pays due tribute. They were all great men in the eyes of the Public Health Service, but Sir John Simon was the greatest of them all. As the English Parliament is the mother of Parliaments, so English public health is the mother of all public health, and this is due almost entirely to Sir John Simon. That the English public health organisation is what it is to-day, the finest in the world and adopted as the model by every civilised nation, is largely thanks to him. This Sir George Newman acknowledges. He recognises also the greatness of the task before the new Ministry, and admits, though many hard things have been said of it, that the Local Government Board did work of tremendous value to the country and the people, and, "with all its limitations of machinery, proved itself a body in search of truth and having humanitarian ends." One precious possession it gave was the gift of method—"a method formulated by practice and experience, which consists of a combination of scientific work and common-sense administration, both associated with a wide and comprehensive vision." As to the future medical plans of the Ministry Sir George Newman has little to say except that steps have been taken to reorganise the medical arrangements by enlarging the staff and differentiating its functions. For the report itself Dr. G. S. Buchanan, Dr. R. J. Reece, and the Medical Inspectors of the Board are responsible, the first-named providing a general survey, as well as dealing, like each of his colleagues, with certain of the special conditions or subjects he was called upon to investigate during the year.

The bulk of the articles included relate to epidemic disease, and the outstanding feature of the year in this connection having been the pandemic of influenza, not unnaturally much space is devoted to this disease, the duty of reporting upon it being imposed upon Dr. Carnwath, who acted as secretary of the special committee set up to investigate the subject. This report contains an admirable and concise description of the outbreaks experienced here, and contains much most useful information with regard to the natural history of the disease. Reference is made to a number of investigations, bacteriological and epidemiological, carried out in various parts of the country during the epidemic. So far as the former are concerned, it cannot, as Dr. Carnwath states, "yet be stated that unequivocal conclusions have been reached." Serious doubt, however, was cast upon the claims of the bacillus of Pfeiffer, which for years had been held to be the causative organism, to continue to be so regarded. So far as epidemiological investigations were concerned, attention is directed to those carried out in Leicester by Dr. Arnold, one of the Medical Inspectors, and in certain public schools by Dr. Macewen, also a Medical Inspector. In Leicester Dr. Arnold made more or less of a general inquiry with the view of eliciting information as to age incidence, while in the schools Dr. Macewen went into the question of immunity in influenza. Neither investigator appeared to succeed in obtaining any information of practical value.

For a section of the report dealing with epidemic diseases associated specially with war conditions Dr. Buchanan is responsible; while Dr. Reece and Dr. MacNalty treat of encephalitis lethargica, the condition which the Press at first insisted upon regarding as botulism, and now persistently and, for some reason or other, jocularly refers to as "sleeping sickness." Of the war-diseases those specially dealt with are typhus and trench fever, malaria and dysentery. The fact that the first two are louse-borne diseases is stressed, and in regard to malaria it is pointed out that, though a few cases of indigenous origin have been brought to light, only in Kent was there any considerable spread of the disease. In the report on encephalitis lethargica Dr. Reece deals with prevalence, and Dr. MacNalty with the general features, of the disease. By both observers a number of references are made to instances of multiple cases in families and institutions, but both quite definitely hesitate to class the condition as infective. Dr. MacNalty's explanation of the sporadic distribution, that it belongs to the group of maladies, including such conditions as cerebrospinal fever (spotted fever) and acute poliomyelitis (infantile paralysis), in which the agent is present commonly in the body and inactive until immunity breaks down, is one likely to be generally accepted.

Apart from reports upon diseases, there are some others dealing with more general matters. Of these, two calling for special reference are that by Dr. Wheaton on maternity and child welfare, and that on the work of the inspectors of food by Dr. MacFadden. Both chronicle advances and improvements. Dr. Wheaton shows that there is a steady increase in enthusiasm for welfare work amongst local authorities, as evidenced by the appointment of more and more health visitors and by the establishment of more and more centres, consultations, crèches, and day nurseries. The work of the food inspectors on behalf of the Army and the people, Dr. MacFadden states, was carried out with great activity, and, if it did nothing more, showed many openings for reforms. Of two important, long-overdue reforms, one has relation to the inspection of home-killed meat, which is inadequately done, because only just over a hundred local authorities have established public abattoirs, and much slaughtering is still done in private slaughterhouses. The other matter calling for attention is the supervision of places where food is prepared or stored. In most districts there are many places in which food is dealt with where the conditions are undoubtedly very bad. From time to time such places are discovered and efforts made to deal with them, but, as Dr. MacFadden shows, proper supervision is impossible for the reason that the powers granted by the Health Acts are inadequate and unsuitable for controlling them, and, more important still, the local inspectors are too few in number and too much overloaded with work of other kinds.

The whole report is exceedingly interesting, and in no sense inferior to those of former years. As it was the last of the series, no doubt those responsible for it desired to see it maintain the high level of excellence already attained, and they have succeeded.

Education of Engineers.[1]

THE report on the education and training of electrical engineers is a really important and instructive pronouncement. The industry is a comparatively new one, and the committee has been able to formulate recommendations in advance of the prejudices and customs of older branches of engineering. An attempt is made to lay down a uniform system for manual and technical workers of various grades, and it is pointed out that industry should be represented on all committees concerned with primary, higher, and technical education and with after-care and juvenile employment. The committee recognises four classes of apprentices, namely:

(1) *Trade Apprentices*, who enter works between fourteen and sixteen and are to be trained to become skilled workmen. They should be selected at an interview and given a trial period. The committee suggests that they should be placed under the supervision of a trained officer responsible for their selection, who should keep records of their progress.

(2) *Engineering Apprentices*, who enter works between the ages of sixteen and eighteen, chiefly from the higher secondary schools. These should be trained by practical experience and technical education, up to the age of twenty-one, for junior staff positions. Before entering works they should have attained a standard equivalent to that of a university matriculation examination. They should be selected after an interview and examination of school records, and appointed for a probationary period. Their practical training should be directed not so much to making them skilled workmen as to giving them a knowledge of various manufacturing processes and of design, testing, and workshop organisation. Their technical education should be continued during apprenticeship by part-time courses.

(3) *Student Apprentices*, preferably graduates in engineering, who enter the works between the ages of nineteen and twenty-two, and should be definitely trained for senior positions on the staff. The committee has reached the conclusion that the need for attracting men of ability makes it imperative, not only to abolish the premium system, but also to give during apprenticeship a maintenance allowance. Student apprentices should, if possible, have graduated in honours in engineering, and be taken systematically through a group of related departments.

(4) *Research Apprentices*.—Research is now an essential factor in industrial progress, and it is necessary to make definite provision for the training of research workers. University graduates who have shown special aptitude for scientific investigation should be selected, preferably from those who enter as student apprentices. In the last year of apprenticeship they should devote attention to investigations arising in practice, and then return to the university for a year of post-graduate work or obtain equivalent experience in a works laboratory.

The report concludes with a discussion of the need for more scholarships from primary to junior technical and secondary schools, and from these to the technological faculties of the universities; also for post-graduate research.

The report of the Institution of Naval Architects is briefer and less systematic. So far as it goes, it is on the same lines as the electrical report. It states that an apprenticeship, or at least a clear understanding binding on both sides between employer and lads entering works, is desirable. It suggests selection on results of school work and the need for a supervisor of lads learning their business. An appendix contains information obtained from the principal shipbuilding firms as to the opportunities afforded by them to lads entering the works, and especially as to the inducements held out to them to improve their educational equipment. An interesting part of the report is an account of the admirable system of training established by the Admiralty in H.M. Dockyards.

Institution of Naval Architects. Report of the Committee on the Education and Training of Apprentices in Shipyards and Marine Engineering Works.

Tropical Control of Australian Rainfall.

IT would appear probable that the Australian continent, extending well within the tropical belt, of approximately symmetrical shape, and free from disturbance by large land masses, especially to the east and west, is the very best place to study the mechanism of tropical rain control. Certainly such a control, if proved and reduced to a system, should very greatly assist the forecasting of the all-important Australian rainfall. Bulletin No. 15 of the Commonwealth Bureau of Meteorology is devoted to a study of this subject by Mr. E. T. Quayle, Supervising Meteorologist of the Melbourne Bureau.

It must be admitted that the period dealt with, largely confined to the six years 1911–16, seems to demand very strong evidence to justify a general conclusion. This objection is partly met by an addendum dealing to some extent with longer periods—up to twenty-four years in one instance—but one would be inclined to wait for confirmation of the great improvement in rain-forecasting claimed by Mr. Quayle. His chosen "argument" is the minimum temperature in the tropical regions of Australia. If this is high, it may be attributed to cloudiness, extra humidity, or north-east wind, and of these three the second is suggested as the most important. In any case, the idea is that this high minimum, which is usually persistent for a few weeks at a time, causes such a flow of air to the southern parts of the continent that the approaching cyclonic "lows" are compelled to part with rain.

The stations on which Mr. Quayle lays most stress for his prediction are Darwin and Mein, the latter being on the north-east coast of Queensland. The influence does not travel directly southward, but Mein corresponds more closely with the Darling district of New South Wales and North Victoria; while Darwin corresponds with South Australia and, to a much less extent, with Western Australia. Inasmuch as the Darwin temperatures are inclined to follow those of Mein after about three days, the inference is that a longer forecast can be made from the Mein figures, or possibly from figures further eastwards in New Guinea.

Mr. Quayle gives figures to show that the average daily rainfall over the southern inland areas during the months April to October (the wheat-growing period) is more than twice as great during periods of high minimum at Darwin as during periods of low minimum. He considers that the slowness of the changes at Darwin justifies forecasts twenty days ahead. He discredits barometer readings as quite untrustworthy for this purpose. The behaviour of the lines of influence is not the same in dry years, but is nearly north to south in wet years. The exceptional years 1914 and 1916 happen to be included in the short period under consideration, and these certainly

show up in the diagrams connecting tropical temperatures with rainfall in New South Wales, South Australia, and the Upper Darling. Tinted diagrams are given showing for the whole continent the monthly departures from mean minimum temperature and mean rainfall, except for the summer months when rain is inappreciable. W. W. B.

Prehistoric Man and Racial Characters.

THE annual meeting of the Prehistoric Society of East Anglia was held on March 23 at the rooms of the Geological Society, the members of the Prehistoric Society being the guests of the Royal Anthropological Institute. The chair was taken by Prof. J. E. Marr, who delivered his presidential address. His subject was "The Relationship of the Various Periods of Prehistoric Man to the Great Ice Age." He regarded the existence of Pliocene man in East Anglia as proved, and also accepted Mr. Reid Moir's views that the "Mid-Glacial" implements of Ipswich were of Lower Palæolithic age, and that Lower Mousterian implements were incorporated in the Chalky Boulder Clay. He brought forward confirmatory evidence of this from the drainage area of the Great Ouse basin, and regarded the Chelles-Archeul period as intermediate between the two glaciations marked by the Cromer Till and Chalky Boulder Clay respectively. After the formation of the latter clay there seemed to be a recession of ice followed by a re-advance in Magdalenian times, but, as O. Holst argues, this need not indicate an inter-glacial period. If there was a Pliocene glaciation in this country, the evidence seems to point to two succeeding glaciations in Pleistocene times, the last being marked by a period of ice-recession in Aurignac-Solutré times, in which case Lower Palæolithic man lived between the second and third glaciations, and the men of the periods from Mousterian to Magdalenian inclusive during the period of the third glaciation, with its interval of temporary ice-retreat. The questions of earth movements and diversions of river drainage during the periods under consideration were briefly considered.

The presidential address was followed by a paper by Mr. H. Dewey entitled "Flat-based Celts from Kent, Hampshire, and Dorset," dealing with a group of implements that were found lying on the surface in various parts of those counties. They differ in outline from one another, but agree in possessing flat bases. Some of the bases were produced by the removal of a single flake, and retain the terminal cone of percussion. Others resulted from the removal of a number of flakes from the sides of the implement, with the obvious intention of making the base level and flat. Most of them are pointed at one end, and have a horizontal chisel-edge at the opposite extremity. In their general form they resemble fat slugs or caterpillars. Sir John Evans figures some examples. Their age is unknown, but would by most archæologists be assigned to the Neolithic period. The discovery, however, in gravels of similar forms renders hasty classification hazardous.

A very fine collection of stone implements from Grime's Graves was exhibited by Dr. A. E. Peake.

In the evening, at a joint meeting of the Royal Anthropological Institute and the Prehistoric Society of East Anglia, Sir Everard im Thurn in the chair, Prof. Arthur Keith gave an address entitled "How Far can Osteological Characters Help in Fixing the Antiquity of Human Remains?" Certain characters of the nose, orbit, palate, and lower jaw have never been seen in British skulls belonging to any period older than the Roman occupation, and become increasingly frequent as we approach the present time. These characters consist of (1) the "margination" or flanging of the lower border of the nasal opening; (2) the retreat of the incisor part of the alveolus of the upper jaw, leaving the nasal spine and lower margin of the nose as an overhanging jib and ledge; (3) the reduction in size of the malar bone, leading to the lower margin of the orbit being depressed in a downward and outward direction; (4) the arching of the upper margin of the orbit; and (5) a reduction in the development of the angular part of the lower jaw. If these characters are found in a British skull, the conclusion may be drawn with certainty that it is of a Roman or post-Roman date. Contraction of the palate was also a character unknown in Britain until a Late Celtic date. The rounded type of head found in graves of the beaker period in Britain were not known in England before Late Neolithic times, but pure representations of this type of skull are still to be seen in our modern population. A type of skull was found in the deeper deposits of the Thames bed which were identical with the skulls found under the Neolithic pile-dwellings of the Swiss lakes. So far as our knowledge of Neanderthal man will take us, we are justified in regarding him as confined to the Mousterian period of European culture. If any characteristic part of the skull or skeleton of this race were discovered in an undisturbed deposit, that deposit may be safely assigned to the period of the Mousterian culture.

A College of Tropical Agriculture.[1]

A STRONG Committee was appointed in August last to report to the Secretary of State for the Colonies upon the desirability of establishing a tropical agricultural college in the West Indies and upon matters connected therewith. Its report has just appeared, and is one which may be fraught with important results for the future of agriculture in our extensive tropical Dependencies, more especially in the West Indies, where, thanks to the work of the Imperial Department of Agriculture, general agricultural prosperity has in the last two decades been placed upon a much sounder footing. It is significant of the trend of modern practice that a Committee like this, composed of planters, commercial magnates, and scientific men, as well as administrative officials, should have reported unanimously in favour of the establishment of such a college.

The selection of a site affords much ground for discussion, and after careful consideration Trinidad was chosen as being near to the headquarters of the Imperial Department, and having good communications with the other islands, besides a great variety of crops in cultivation. Incidentally, in view of the growing importance of oil in that colony, a subsidiary school of oil technology is proposed. A postscript to the report, however, suggests that the last word may not yet have been said on the subject of location.

A governing body of about twenty-three, representing all the different interests involved, is proposed, and a staff of ten professors (agriculture, mycology, entomology, agricultural chemistry, organic chemistry, agricultural bacteriology, agricultural and physiological botany, genetics, sugar technology, and agricultural engineering and physics), besides lecturers in stock and veterinary science and in bookkeeping.

Considerable interest attaches to a curriculum sug-

[1] West Indies. Report of the Tropical Agricultural College Committee. (H.M. Stationery Office, 1920.) Price 2d.

gested by Sir Francis Watts, the Imperial Commissioner of Agriculture for the West Indies, with which the Committee expresses itself as in general agreement. It includes (*a*) a junior course of two or three years, suitable for boys leaving the Colonial secondary schools and intending to follow ordinary agricultural pursuits, usually in the colonies from which they have come; (*b*) a senior course of similar instruction of not less than four years; (*c*) a two years' course, practically the same as the last two years of the previous course, for students who have already undergone a training in agriculture in a university or agricultural college, and thus intended to meet the case of students going out from Europe to work at agriculture in the tropics, whether on their own account or as officials; and (*d*) post-graduate study of special agricultural subjects, such as mycology or genetics, or the study of special crops such as sugar or cacao. It is incidentally recommended that a special school for the study of sugar should be established.

This is a very interesting and practical programme, and it is to be hoped that it may soon be translated into reality. The only criticism that occurs to one is to ask whether it is not just a trifle too ambitious for a commencement and too great a change from the customary methods of learning the work of tropical agriculture, and whether it may not tend to make the tropical student at least, and especially him who must work under seniors trained in the old way, a trifle unpractical. Great care will have to be exercised to make the instruction as practical as possible, and for this reason we note with pleasure the insistence upon making the new college work as much as possible in connection with the Imperial Department.

Finally, it is suggested that a fund of at least 50,000*l*. be raised by private subscription for the establishment of the college, and that for maintenance annual contributions be invited from the various Colonial Governments, and also from the Imperial Government, to which the proper development of the great tropical lands of the Empire is of such paramount importance.

Duplex Wireless Telephony.

ANOTHER of the interesting series of papers on wireless developments connected with the war before the Wireless Section of the Institution of Electrical Engineers was that of Capt. P. P. Eckersley, read on March 17, describing experiments by Major Whiddington and himself on the application of duplex wireless telephony to aircraft. The advantages of being able to converse freely and simultaneously both ways, as is done in a true duplex system, over using a change-over switch are obvious, but the electrical difficulties in the way of its successful accomplishment are considerable. The main problem lies in devising a form of circuit which will protect the receiver, without detriment to its efficiency, from the effects of the relatively powerful high-frequency alternating currents generated by the transmitter.

Two general principles have been adopted. In one, two separate aerials with different frequencies for transmission and reception are placed at right angles and spaced more than a quarter of a wave-length apart. In the other, which may employ a single aerial, the "earth" connection is split, and the branches are tuned so that the transmitter current passes through one and the receiver current through the other. Both these systems present difficulties, and have been used only to a limited extent. A compromise system, in which the transmitter oscillates only when the operator is actually speaking, with what is called a "quiescent aerial" was also experimented with, but the speech was found to be much improved by allowing a small permanent oscillation, increased sympathetically with the voice. Such an arrangement, called an "augmented oscillation transmitter," has certain practical advantages, as well as incidentally presenting some interesting theoretical points, but forms only a "partial duplex" system, as an interruption during speaking cannot be heard. The author's experiments have progressed well on the way towards the evolution of a practical and trustworthy system of duplex wireless telephony for aircraft, and form a valuable groundwork for future development.

University and Educational Intelligence.

ABERDEEN.—At the spring graduation ceremony Principal Sir George Adam Smith announced a gift of 20,000*l*. from Sir Thomas Jaffrey, head of the Aberdeen Savings Bank, for the establishment of a chair in political economy in the University. There has been a lectureship in this subject for a number of years.

The University has just conferred on Sir Jagadis Chandra Bose the honorary degree of LL.D.

BIRMINGHAM.—Mr. Arthur R. Ling, consultant in applied chemistry and lecturer in brewing at the Sir John Cass Institute, London, has been appointed to the Adrian Brown chair of brewing.

A bronze memorial tablet in memory of the late Prof. Adrian Brown has been erected in the Brewing School by past students.

A gift has been received from the Asiatic Petroleum Co. of a model drilling equipment, which will be exhibited at the forthcoming Petroleum Exhibition at the Crystal Palace.

Mr. Frank Shaw has been appointed assistant lecturer in electrical engineering, and Mr. Raymond B. H. Wyatt lecturer in bacteriology.

CAMBRIDGE.—Mr. G. E. Briggs, St. John's College, formerly University Frank Smart student in botany, has been elected to the Allen scholarship.

The new Statute of the University which gives the degree of Ph.D. to research students in the University is the result of the work of a syndicate appointed in December, 1917, "to consider the means of promoting educational collaboration with the universities of the Empire and foreign universities." The chief points of interest in the proposed regulations for working the Statute are as follows:—Research students, who must be at least twenty-one years of age on admission, must have graduated at some university (Cambridge itself included), or must satisfy the University as to their general educational qualifications. Before admission their proposed course of research must have been approved, and they must show that they are qualified to enter upon the course proposed. Students must pursue research for three years before submitting for a degree the dissertations embodying the results of their research. Those who are graduates of Cambridge need only spend one of the three years at Cambridge; others must spend at least two years at Cambridge. The remainder of the time must be spent at some place or places of study approved by the University. Research students who are candidates for degrees at other universities and who spend at least two terms in Cambridge may receive certificates of regular study and industry to cover the time spent in Cambridge. A Board of Research Studies is to be formed to supervise the carrying out of the new scheme. The proposals show a welcome movement away from the old spirit of "splendid isola-

tion" which has in the past too often been attributed to Cambridge University.

LONDON.—Mr. William Neilson-Jones has been appointed as from May 1 next to the University chair of botany tenable at Bedford College. Mr. Neilson-Jones was foundation scholar of Emmanuel College, Cambridge, and obtained a first class in part i. of the Natural Sciences Tripos and a second class in part ii. (Botany). He has carried out research work at Cambridge and for the Health of Munition Workers Committee of the Medical Research Committee. In 1909 Mr. Neilson-Jones was appointed lecturer in botany at University College, Reading, and in 1913 assistant lecturer in botany at Bedford College; since 1916 he has been head of the department at this college.

It has been resolved by the Senate that the following posts should be established in connection with the recent benefaction of 150,000*l.* made by the Sir Ernest Cassel Trustees:—(1) Sir Ernest Cassel chairs of accountancy and business methods, of commercial and industrial law, and of banking and currency; (2) three Sir Ernest Cassel readerships in commerce, dealing specially with (*a*) foreign trade, (*b*) the organisation of industry and trade in the United Kingdom, and (*c*) the influence of tariffs and taxation respectively; and (3) three University lectureships in commerce, with special reference to commercial geography, business methods, and transport respectively.

An offer from the Worshipful Company of Vintners to provide, for a period of five years in the first instance, two scholarships, each of the annual value of 150*l.*, for students for the degree in commerce has been accepted by the Senate with thanks. The thanks of the Senate have also been accorded to the relatives of the late Capt. G. D. Harvey-Webb, formerly of University College, for their gift of his collection of shells for the department of zoology at that college; and to Prof. Graham Wallas for his gift of another collection of shells for the same department to supplement that of Capt. Harvey-Webb.

The following doctorates have been conferred:—*D.Sc.:* Mr. F. J. North, an external student, for a thesis entitled "On Syringothyris, Winchell, and Certain Carboniferous Brachiopoda referred to Spiriferina, d'Orbigny." *D.Sc. (Economics):* The Rev. A. W. Parry, an external student, for a thesis entitled "Education in England in the Middle Ages."

Keddey Fletcher-Warr studentships, each of the value of 300*l.* a year for three years, have been awarded to Dr. Agnes Arber, for post-graduate research in botany, and to Miss Margaret McFarlane, for post-graduate research in psychology. These studentships were established under the benefaction founded by Mrs. du Puy Fletcher.

The annual report of University College has just been issued. The total number of students for the session 1918–19 was 2048, an increase of 977 on the previous year. This increase took place after the armistice, and mainly in January, 1919, and consisted almost exclusively of ex-Service men. The total revenue of the college for the year 1918–19 was 75,781*l.*, of which 26,304*l.* was from fees. The total expenditure was 77,824*l.*, causing a deficit of 2210*l.* This deficit arises from the increase in salaries that has become necessary, and generally from the increased cost of running the college. The report contains a summary of the main work of the year. The new departments of Scandinavian studies and of Dutch studies have already made a good start. The new school of librarianship, which has been instituted with money provided by the Carnegie Trust, and of which Sir Frederic Kenyon is the honorary visitor, began with an enrolment of eighty-eight students. The student body included 253 post-graduate and research workers. The fifth appendix of the report gives a list of the papers and publications issued by them during the past year. Nine new fellows are elected to the college biennially. The list for this year is remarkable in that it includes the first Chinaman to be elected to the fellowship and two distinguished members of the Slade School of Fine Art. The full list of fellows is as follows:—F. J. Fitzmaurice Barrington, W. C. Clinton, Ethel M. Elderton, Brig.-Gen. Sir Alexander Gibb, his Excellency Yuen Hsu, Augustus E. John, Major Sir William Orpen, Dr. T. H. C. Stevenson, and Dr. Ethel N. Thomas.

MANCHESTER.—In connection with the Ellis Llwyd Jones lectureship for training teachers of the deaf recently established at the University through the benefaction of Sir James E. Jones, the Carnegie United Kingdom Trust has granted to the University the sum of 2500*l.* for the foundation and maintenance of a library for deaf education. It is intended to make this library as comprehensive as possible, and to include in it works dealing with the various systems of teaching the deaf, speech training, psychology of speech and of hearing, phonetics, acoustics, anatomy, physiology, and diseases of the ear. The books are to be available to all individuals, societies, and institutions throughout the United Kingdom interested or concerned in the education and training of the deaf, and they will be ready for consultation and borrowing immediately after Easter. No charge beyond the cost of carriage is to be made for the loan of books, but intending borrowers will be required to fill in a form of application to be obtained from the Librarian, Library for Deaf Education, The University, Manchester.

OXFORD.—The Romanes lecture for 1920 will be delivered by the Very Rev. W. R. Inge, honorary fellow of Hertford College, Dean of St. Paul's, on Thursday, May 27. The subject will be "The Idea of Progress."

Societies and Academies.

LONDON.

Aristotelian Society, March 8.—Prof. Wildon Carr in the chair.—M. **Ginsberg**: Is there a general will? The term "general will" has been used in many different senses. Especially important are the view of Wundt based on an analysis of the mutual implications of presentation and will, and leading to a theory of a series of will-unities of varied complexity, and the doctrine of a "real" will worked out by Prof. Bosanquet and other idealists. All the theories, in varying degrees, involve a confusion between the act of willing, which must always be individual, and the object of will, which may be common. Prof. Bosanquet's view in particular is based upon a hypostatisation of contents, and a tendency to deny the reality of acts, of experience. Generally, in so far as the psychological forces operative in society are general they are not will, and in so far as there is present self-conscious volition it is not general. The State and other associations exhibit a kind of unity, but this unity is a relation based on community of ideals and purposes, and must not be spoken of as a person or will. For the purpose of social theory, what is required is not a common self, but a common good. The latter is an ideal and not an existent, and must not be identified with a general will.

Mineralogical Society, March 16.—Sir William P. Beale, Bart., president, in the chair.—A. **Russell**: The occurrence of cotunnite, anglesite, leadhillite, and galena on fused lead from the wreck of the fireship *Firebrand*, Falmouth Harbour, Cornwall. The specimens were obtained in 1846 from the wreck of the fireship *Firebrand*, which was burnt in Falmouth Harbour about the year 1780. They were found under the lead pump, most of which appeared to have been melted and mixed with charcoal, and consist of slag-like masses of lead, which has evidently been fused, and upon the surface and interstices of which are numerous well-defined and brilliant crystals of cotunnite and anglesite, and more rarely small crystals of leadhillite and galena. The cotunnite crystals, which are colourless and transparent, with brilliant faces, are nearly always elongated in the direction of the *a* axis, and attain a length of 3 mm. The habit is somewhat variable owing to the very unequal development of the faces. The forms observed were 010, 001, 021, 011, 012, 101, 111, and 112. The anglesite crystals are of rectangular habit, and exhibit the forms 100, 001, 110, 102, 122, and 113. The leadhillite crystals, thin six-sided plates in shape, are of a brown colour, and show the forms 101, 201, $\bar{1}01$, 201, 112, 111, $\bar{1}12$, and $\bar{1}11$. The galena occurs in minute cubo-octahedra. An occurrence of cotunnite formed under almost exactly similar conditions has been described by A. Lacroix. Similar occurrences of lead oxychlorides at Laurium and of leadhillite in Roman slags from the Mendip Hills were referred to.—W. Campbell **Smith**: Riebeckite-rhyolite from North Kordofan, Sudan. A rock found by Dr. C. G. Seligman at the base of Jebel Katul, 350 miles south-west of the Bayuda volcanic field, was described. Dr. G. T. **Prior**: The meteoric iron of Mount Ayliff, Griqualand East, South Africa. This meteoric iron, found about 1907, is a coarse octahedrite similar in character to Wichita County (Brazos River) and Magura (Arva). On polished and etched surfaces it shows nodules of graphite and troilite, and abundant cohenite crystals arranged parallel to the octahedral bands. It contains about 7 per cent. of nickel.

The Universities

MORE than a year ago—on February 20, 1919—an article on "Education in the Army" was published in these columns in which urgent reasons were advanced for a new policy. During the intervening period, numerous contributions have been made to various newspapers and reviews on the same subject, and book has succeeded book animadverting on the educational defects of the Army organisation as revealed by the war. Great disappointment will be felt that these sincere representations have so far produced no more useful result than the Memorandum on the Army Estimates of 1919-20, recently published by the War Office "in amplification of the speech of the Secretary of State in introducing the Estimates." That speech, delivered by Mr. Churchill on February 23, was able and serious within somewhat exiguous limits, but it contributed nothing to the question of educational reform in its military aspects. We are forced, therefore, to turn to the amplifying Memorandum in the anxious hope of finding the question discussed on broad lines and in a scientific spirit. It proves to be a Mother Hubbard cupboard containing only a schoolboy essay freely embellished with mixed metaphors. Thus:

"One of the important lessons of the war has been the extent to which the Army is dependent on the Universities. Great strides were made in this direction before the war, with the result that the Universities responded to the call for help in a splendid manner."

This belated recognition of the valuable work of the Universities in connection with the war is well and fair so far as it goes, but it affords no guarantee to the British public, whose ears are still attuned to the sad diapason of the war's tragedies, that the reorganisation of the Army on its educational side is to be taken seriously in hand. The fact that the Secretary of State, in his speech, found the subject unworthy of even a passing reference is surely disconcerting.

We pointed out recently that the Memorandum deserves to be commended for the proof it affords of the recognition by the Army of the importance of scientific research conducted both under its direct supervision and in our Universities and colleges. Every science and every scientific worker can make some contribution to national defence.

To give Mr. Churchill his due, he appears to realise the economy of men and money which may result from new applications of science. He quoted in his speech, as an example of the possibilities of the Air Force, the case of the recent Somaliland campaign, which, at a cost of 30,000*l.*, achieved much more than an expedition before the war which cost 2,500,000*l.*; and he described a new form of tank, which, so far from damaging the roads, actually improved them, and possessed an engine which, instead of overheating the interior, exercised a refrigerating effect. But what we ask, and what we shall insist on knowing, is whether this new spirit is to permeate the whole Army, or whether, when the wounds of war are healed and its bitter memories pass into subconsciousness, the Army will revert to its old traditions.

Fortunately for the Army and for the nation, one of the root causes by which these traditions were fed has been effectively removed. Before the war, officers were not paid a living wage, and that system was deliberately perpetuated in order to maintain the tradition of the officer as a gentleman of means and leisure who did half a day's work for half a day's pay. As a writer in the *New Statesman* observed (January 25, 1919):

"It is no use pretending now that the system gave us an efficient Army. One does not gather grapes from thorns. The ablest boys in the country's schools went almost invariably into other callings. Some few officers, with the German menace before their eyes, did indeed work with most praiseworthy, unpaid energy in the years immediately preceding the war. But no gratitude to the 'Old Contemptibles' should blind us to the fact that, however devoted their officers were, they were clearly outclassed as professional men, both by their German opponents and by their French Allies; and that in spite of the unique opportunities afforded by Colonial and Indian war experience."

Under the revised rates of pay of Army officers, a junior subaltern receives pay and allowances amounting to 320*l.* a year if unmarried, or 394*l.* if married, and is able to look forward to generous increments on promotion and to an adequate pension. It will be a breach of trust if, under these conditions, the Army Council does not propose far-reaching reforms as regards standards of education and training for the commissioned ranks.

There is no reason why a standard of professional training at least equal to that required by other professions, such as medicine and engineering, should not be required by the Army, and the only imaginable obstacle to this reform are the protests of old Regular officers, who think that the system which produced them must be the best possible. That particular obstacle has been overcome more than once in the history of the British Army, and it should not deter Mr. Churchill if he will devote to this reform some of the energy which he expends so generously on more forlorn objects.

To pass from destructive to constructive criticism, we would urge that the standard of education represented by three years' study at a University should, as a general rule, be demanded of all Army officers; in other words, that the raw material for the commissioned ranks should be University graduates rather than public-school boys. The military colleges at Woolwich and Sandhurst should no longer be used as seminaries for the elementary education of adolescents.

A great economy of public money would be effected by this simple reform. According to the Estimates for 1919–20, Sandhurst for 700 cadets will cost a gross amount of 195,350*l.*, being 279*l.* 1*s.* 5*d.* per cadet per annum, while Woolwich for 280 cadets will cost 86,850*l.*, or 310*l.* 3*s.* 7*d.* per cadet per annum. It is "pure" education which these young men chiefly require; they should obtain it in the Universities, which can offer a wide variety of curriculum and abundant facilities for social intercourse with all types of student. The University contingents of the Officers Training Corps are admirably adapted for providing elementary military training, which could be supplemented within the Army before and after the student takes his commission. Incidentally, the Army would be able to select for its commissioned ranks mature men possessing a livelier sense of vocation than can be expected from schoolboys.

If the quality of the raw material were improved in the way suggested, there should be no ground for nervousness as to the finished product. Methods could easily be devised of advancing and specialising the military training of these young University graduates. In time a *corps d'élite* would be formed able to study the art of war in all its aspects and to apply new scientific ideas and discoveries to national defence.

Woods and Water Supply.

Forests, Woods, and Trees in Relation to Hygiene. By Prof. Augustine Henry. (The [illegible]) Pp. xii+314. (London: Constable [illegible], Ltd., 1919.) Price 18*s.* net.

PROF. HENRY writes of forests, woods, and trees with an enthusiastic appreciation of the beneficent part they play in the economy of Nature and in the service of man. He has devoted great energy to the study of his subject, and collected data of much value which will prove very useful to those engaged in projects of afforestation in this country. The importance of the subject is, we believe, fully realised by the Government, and Prof. Henry adduces so many instances of local authorities which have begun to move in the matter that we may hope to see the restoration of the woods on waste lands making steady progress year by year.

The book before us is an amplification of the Chadwick Lectures delivered by Prof. Henry at the Royal Society of Arts in 1917, and the author no doubt looks upon it in large measure as propaganda in the cause of tree-planting on a national scale. The first three chapters, however, deal with matters of profound scientific importance—the influence of forests on climate, the sanitary influence of forests, and forests as sites for sanatoria. These are difficult matters, as Prof. Henry fully realises, and some of them have agitated students of physical geography for generations. The difficulty of the question of the influence of forests on climate arises in great measure from the fact that climate has a great influence on forests, so that in wooded areas the interplay of cause and effect becomes extremely complicated.

Prof. Henry has read up the subject widely, but the nature of his book makes it impossible for him to focus the results sharply enough. He abundantly justifies the thesis that an increase of forest growth is of national importance for improving the hygiene and the economic condition of this country; but he scarcely attempts a scientific demonstration of the mechanism by which the beneficial effects are produced. He does, indeed, direct the attention of his readers to many recent investigations which it is most useful to have brought together, and for this guidance the student who wishes to go farther should be sincerely grateful.

We cannot, however, accept the results of some of the series of observations referred to without a more critical discussion of the methods employed and the data recorded in different parts of the world. In particular we agree with Prof. Henry in his opinion that the effect of afforestation in

increasing the general rainfall is probably negligible in the British Isles.

The greater part of the volume is devoted to a question of national importance—the afforestation of water-catchment areas, with particulars of the extent to which the work has already proceeded. This is timely, for the whole question of the water resources of the country is now under investigation by a Committee appointed by the President of the Board of Trade and the Minister of Health. Prof. Henry shows clearly that the gathering grounds for the reservoirs of water supply by gravitation are well fitted in almost every case for planting with timber-trees up to an elevation of 1000 ft., and he adduces some evidence to show that covering a certain proportion of the surface with forest growth, so far from being detrimental to the yield of the areas, is even helpful. Curiously enough, he does not refer to the important influence of high vegetation, and especially of trees, in precipitating moisture from mist, a phenomenon which is shown very strikingly when one is traversing a road through a wood in a thick mist. The road remains perfectly dry, while the drip of water from the branches on either side gives out the sound of abundance of rain, and the ground beneath the trees soon becomes saturated. As Dr. Marloth proved on Table Mountain many years ago, even such inconspicuous growths as a bed of reeds can draw liquid streams from a cloud drifting along mountain slopes which would deposit nothing on a bare stretch of soil or rock. No doubt a certain amount of water is in this way added to a forest-covered catchment area without being recorded in properly exposed rain-gauges.

On the other hand, if, as certain experiments made in Germany and quoted on p. 3 seem to suggest, the transpiration of forest trees is greater than the evaporation from an exposed water surface, the net result may be to reduce the amount of water reaching a reservoir, and this might be a serious matter in a dry summer. Even if we admit that afforestation does not appreciably increase the available run-off, it seems unlikely that it can seriously diminish it, and the balance of probability is that planting a water-catchment area is beneficial. A wide belt of woodland surrounding a reservoir must reduce the wash of surface material into the streams, and so retard the silting up of the reservoir. But, what is more important, the value of the forests when once established will justify the acquisition of the whole drainage area of their water supply by authorities which could not otherwise justify the expense of such a step; and it is only on ground which is the property of the water authorities that it is possible to keep the area free of population or of farm stock, and so secure the water absolutely from all sources of pollution.

This is scarcely the place to criticise the list of catchment areas for water supply in the United Kingdom, which fills 135 pages, and appears to be based on official figures; but one cannot help regretting that the data quoted are not more homogeneous. Rainfall figures, for instance, are given only in some cases, and even then they are often misleading from the lack of information as to how the average was computed. The responsibility for this is on the local authorities themselves, and we can only thank Prof. Henry for his diligence in bringing so many facts together that the room for improvement in the form of statement stares one in the face. No remedy for these ill-assorted statistics can be found until some central water authority comes into existence which can co-ordinate all the local efforts in accordance with one national and scientific system. One slip, however, should be corrected—the allocation of Haweswater to the supply of Penrith on p. 175 and on the map on p. 173. This should be Hayeswater, a small tarn lying between Haweswater and Ullswater.

HUGH ROBERT MILL.

The Wilds of South America.

(1) *In the Wilds of South America: Six Years of Exploration in Colombia, Venezuela, British Guiana, Peru, Bolivia, Argentina, Paraguay, and Brazil.* By Leo E. Miller. Pp. xiv + 428. (London: T. Fisher Unwin, Ltd., 1919.) Price 21*s*. net.

(2) *University of Pennsylvania. The University Museum Anthropological Publications.* Vol. ix., *The Central Arawaks.* By William Curtis Farabee. Pp. 288+xxxvi plates. (Philadelphia: The University Museum, 1918.)

(1) MR. MILLER'S well-illustrated book is the attractively written personal narrative of seven exploring expeditions to South America, all but one sent out by the American Museum of Natural History, mainly to collect mammals and birds.

There are few wild countries left which have not been ransacked with the hope that the amassed specimens may include some species "new to science," but there are still fewer the fauna and flora of which have been correlated intelligently with scientific observation of the prevailing environmental conditions. Several American museums stand in the front rank of such

enterprises, well planned, with, perhaps, restricted but intense purpose. Mr. Miller, of the American Museum of Natural History, was a member, or the leader, of these expeditions, which from the spring of 1911 to the beginning of 1916 covered an enormous amount of ground: Colombia, in which faunistic paradise alone he spent nearly two years; Venezuela and British Guiana; Bolivia and Argentina; and Roosevelt's famous journey. It is worth noting that our active author finished this book in an aviation concentration camp preparing to "do his bit."

This narrative contains no tedious itineraries. It is a condensed account of, in the aggregate, five years' travelling, with many hundreds of episodes, observations, and reflections, which cover a very wide field, from old churches to local industries, people and scenery, plants and creatures, just as he happened to come across them. There are no blood-curdling incidents, although he had his fair share of danger. Since we are taken through steaming-hot tropical lowland forests, over rivers by raft, canoe, or steam launch, across desert plateaux on to snow-covered mountains, to wild natives and modern towns, a few bare samples or headings must suffice to indicate the range of the work:

A successful search in the highlands of Colombia for the "Cock-of-the-Rock," of which beautiful bird's home life, nest, and eggs little was known. Humming-birds becoming intoxicated with the sap of some tree tapped by woodpeckers. A study of the different modes of feeding of various birds as observed side by side: the parrots climbing to the tip of the fruit-laden branch; the large-billed toucans are enabled to reach a long distance for the coveted morsel, whilst the trogons, with short neck, delicate feet and bill, hover about the fruit. Whilst one river was muddy and potable, another, close by, had clear red water, unfit for drinking, and it contained only a few kinds of fish, but no crocodiles, sandflies, or mosquitoes were about.

Mr. Miller suggests that monkeys may keep the malaria infection alive in districts which, because of this plague, are practically uninhabited by human beings.

In some parts of Bolivia vampires were so common and so little shy that the author was able not only to watch their biting and sucking, but also to sweep them off the mule with a butterfly-net—a feat which frightened the suffering beast so much that it sank to the ground with a groan.

The Sirionó tribe in the same country use bows so powerful that the hunter has to lie down, to grasp it with the feet, and to draw the cord with both hands. They are fierce savages, not "Indios reducidos"—*i.e.* not yet broken and cowed—and no wonder. They had fixed some *protégés* of a mission station to trees by means of numerous long thorns. The padre in turn had seven captives tied to posts, and after four of them had died from starvation and sullenness, the priest took pity upon the remaining three and released them.

As usual, the Indian's mind is rather perplexing. A woman asked the exorbitant price of 4 pesos for a fowl, which she said was a first-class game-cock; when told that the bird was wanted for food only, she at once parted with it for 60 centavos.

On a sandstone plateau, at an elevation of 13,400 ft., was growing the gigantic "Puya," one of the Bromelia family, and humming-birds (*Patagona gigas*) hovered over its numerous flowers.

Monstrous lies grow sometimes from a grain of truth, and so do colossal horned snakes in Brazil. Their size at least is proved by a cunning mixture of circumstantial evidence and further reflection: for instance, the discovery by trustworthy hunters that the so-called horned snakes are really not horned creatures, but such as have swallowed an ox tail foremost, the spreading horns ultimately lodging crosswise in the corners of the mouth—quite a sufficient explanation in countries where anacondas are said to grow to 40 metres in length. But there are also very many observations and valuable reflections by the author himself, frequently concerning the supposed working of natural selection. For example, if the struggle for existence is as keen as is often thought, how can the female insectivorous bat, encumbered with her baby fully three-quarters as large as herself, compete successfully with the unhampered males?

There is also an important account of the cowbird's (Molothrus) parasitic habits, compared with which those of our own cuckoo seem insignificant, dozens of eggs being dropped into a single nest of the Owen-bird (Furnarius), so that the latter deserts it.—That human curse of the tropics, the plume-hunters, in Paraguay and elsewhere, now scatter poisoned fish over the egret's feeding-grounds during the breeding season.

(2) Mr. Farabee's work on the Arawaks is one of the volumes containing the results of an expedition, from 1913–16, sent to South America by the Museum of the University of Pennsylvania. It deals in detail with the Arawak tribes, their somatic characters, mode of life, traditions and beliefs, ornaments, weapons and other implements. One hundred pages are devoted to the language.

The general account is most interesting reading, but the book is really intended for the specialist.

There are, however, no fewer than thirty-six plates of excellent photographs, notably those which represent the people and their mode of life. The greater number of Arawaks inhabit the savannahs of southern British Guiana and the neighbouring parts of Brazil. The largest of the tribes is that of the Wapisianas, and they number only about 1200. Others amount to fewer than one hundred each, all rapidly decreasing.

Mr. Melville, magistrate and protector of Indians, has lived amongst them for twenty-five years, guarding them from the unscrupulous exploiter. "No traders or missionaries have yet established themselves amongst them, hence their natural honesty, their simple purity, and their primitive religious ideas have not been destroyed."

The author says that the coincidence between our classical and the Wapisiana interpretation of the zodiacal and other constellations is not to be wondered at. To call Orion the warrior is obvious enough. But the Pleiades are "the turtle's nest full of eggs and father of the rains," the beginning of the June wet season. Spica is the cornplanter; Scorpio, the anaconda; and Antares, the scorpion's heart, a red macaw swallowed by the snake. α Cygni is the kingfisher. α and β Centauri are a hunter with his wife.

Life and Temperature.

Action de la Chaleur et du Froid sur l'Activité des Etres Vivants. By Georges Matisse. Pp. ii+556. (Paris: Emile Larose, 1919.)

M. G. MATISSE has brought together in book form researches made by him on the influence of cold and heat on living organisms. He reminds us of the famous experiments of the Abbé Spallanzani, prince of biologists, who showed that dry rotifers could be submitted to temperatures far below zero and up to 62·5° C., and yet return to active life on wetting. Pouchet tells of the strange views which were mooted concerning the death and resurrection of these animals and others experimented upon by Spallanzani, and how Fontana, for fear of the Inquisition, experimented in secrecy, while the Abbé fearlessly published his results and speculations. Spallanzani crushed frozen eggs of insects with the finger-nail and found that small drops of liquid exuded. Life is preserved in this fluid, a "superfusion" of the colloids and electrolytes of protoplasm, the water freezing out. He found seventeen was the greatest number of freezings and thawings which any rotifers, Tardigrades, or Anguillula withstood. Gradual thawing is essential for the preservation of life. Pictet successfully froze and thawed frogs and fish. Spallanzani was the first to sterilise infusions by heat.

M. Matisse recalls Ehrenberg's observations on oscillaria, infusoria, and rotifers living in hot springs in Ischia at 81–85° C.; life in similar conditions, he says, is found in the Yellowstone Park, Wyoming, U.S.A.

We now know that spores of bacteria withstand 100° C. more than sixteen hours, 115° C. from thirty to sixty minutes, and 140° C. one minute. Not only does temperature count, but also time. Claude Bernard found that pigeons and guinea-pigs died in six minutes when put in a dry oven at 90–100° C., rabbits in nine minutes, and dogs in eighteen to thirty minutes. A woman stayed twelve minutes in an oven at 132° C. without being strongly incommoded. Pouchet mentions a man who, at the old Cremorne gardens, walked through a perforated metal tunnel which was surrounded with burning brushwood.

Adaptation to temperature is of considerable interest. Paul Bert found that fish, raised quickly from 12° to 28° C., died, but that, raised slowly 2° C. a day, they survived up to 33° C. Tadpoles, kept a month at 15° C., died at 40·3° C.; others, kept at 25° C., died at 43·5° C. (Davenport and Castle). Snails survive exposure to −110° to −120° C. for weeks. Spallanzani showed that their respiratory exchange and circulation cease entirely in the cold. Protozoa survive −200° C.; bacteria, −250° C. for ten hours (MacFadyean).

Seasonal polymorphism depending on temperature is of interest—*e.g.* aphis is wingless, and reproduces parthenogenetically in the summer; it becomes winged, and male and female in form, with sexual reproduction, in the autumn. Papilio *Vanessa porosa-levana* has spring and summer forms. Salamanders, on the high Alps, are small and black, and have only two young, which are born without branchiæ; those on the plains are large, blotched with yellow, and have many young born with branchiæ. Inversion of the climatic conditions reverses the characteristics of these two forms (Kammerer). Tower submitted Coleoptera (*Leptinotarsa decemlineata*) at the time of formation and maturation of sex elements to 35° C. and dry conditions. The eggs hatched in normal conditions showed eighty-four mutations in the ninety-eight individuals which reached adult age.

A gasteropod, *Lymnea stagnalis*, reproduces its kind in water cooler than 12° C., but the progeny are small. In water at 15–18° C. the progeny are larger. The character of smallness becomes fixed; small individuals transported from cold to warmer water continue to have small progeny (Semper).

The main part of Matisse's book deals with the consideration of the law of van't Hoff and

Arrhenius concerning the acceleration by temperature of the velocity of chemical reactions, and the relation of this law to biological functions. The author has carried out a large amount of experimental work and correlated it with that of others.

There is an increase, an optimum, and a decrease of many biological functions with temperature, and in several cases the increase over a certain range is comparable with that of a chemical reaction—*e.g.* the segmentation of an ovum, the beat of the heart, or ferment action. The reactions of the living animal are, however, too complicated to come under any simple law.

A University Course in Botany.

Botanical Memoirs. No. 4: *Elementary Notes on Structural Botany.* By A. H. Church. Pp. 27. No. 5: *Elementary Notes on the Reproduction of Angiosperms.* By A. H. Church. Pp. 24. (London: Oxford University Press, 1919.) Price 2*s.* net each.

CONSIDERABLE interest has been shown during the past two years in the reconstruction of botanical teaching at the universities, and it seems opportune, therefore, that one of the older universities should publish in some detail the plan on which its instruction in botany is based in so far as it relates to the elementary courses in this subject. We gather from the concluding note of Memoir 4 that the notes have been written as schedules to accompany, and not to replace, lectures, it being assumed that the lecturer can add explanatory emendations and enlargements on special points. No doubt every teacher will have his own views as to the arrangement of the subject-matter of an elementary course, and will desire to give special emphasis to certain aspects, which he will do by the prominence assigned to such parts of the subject. A somewhat general feeling has been expressed in the recent correspondence on botanical teaching in the pages of the *New Phytologist* that physiological botany has not always received adequate attention or treatment in botanical teaching.

From that point of view it will be noted with interest that the Oxford course of instruction begins and ends in biological features, and is well permeated with physiological considerations. On the whole, however, it may be considered a morphological treatment of the subject, as, indeed, the title "Structural Botany" indicates, though it is apparent that, as in most elementary courses, structure is considered in the light of the functions which the various organs have to perform. Occasionally this mode of treatment might be more closely adhered to. On p. 6, for instance, in dealing with the stem of Helianthus, it is mentioned that the endodermis is "in this stem curiously the only layer with starch," and no reason for this phenomenon is advanced or even suggested at this stage, though much later in the course (p. 24) "falling starch" is referred to as popular since 1900 as hypothesis of statocyte nature.

In connection with the palisade mesophyll no allusion is made to the function of this tissue, nor are any special reasons adduced for the shape and arrangement of its cells. The same criticism applies to the paragraph dealing with the spongy mesophyll. The main criticism, however, which anyone familiar with the difficulties of instructing students within a severely limited time will level against the course is that it attempts too much within the period indicated by the author as available. Considerably shortened, the course might gain in thoroughness of treatment what it would lose in extensiveness. Interesting and enlightening, for example, as are the leaves of Ficus and Nymphæa, the structure and function of a leaf may be learnt from the cherry laurel alone. Similarly in Memoir 5, some of the seeds mentioned, like those of Aucuba, Æsculus, Juglans, and Hedera, are not essential to the proper understanding of the structure of a seed in addition to the two or three more common types. These are only a few of many passages which might be curtailed. No doubt the better plan would be to retain the fuller course and to demand a longer period for instruction, and we heartily sympathise with the author's difficulties when required to supply what he calls "minimum botany" for his students. Possibly under the new *régime* at Oxford this may be remedied. If the facts are as stated in the concluding paragraph of Memoir 5, it is, as the author says, remarkable that in a university of primary importance the teaching of plant biology should be of such a meagre description. We fully share the author's conviction that a knowledge of life in some form should be part of the mental equipment of every educated person.

Recent Mathematical Text-books.

(1) *Unified Mathematics.* By Prof. L. C. Karpinski, Prof. Harry Y. Benedict, and Prof. John W. Calhoun. Pp. viii+522. (Boston, New York, and Chicago: D. C. Heath and Co.; London: George G. Harrap and Co., Ltd., 1918.) Price 10*s.* 6*d.* net.

(2) *Elementary Calculus.* By C. H. P. Mayo. (With answers.) Pp. xx + 345 + xxxix. (London: Rivingtons, 1919.) Price 10s.

(3) *Mensuration for Marine and Mechanical Engineers.* (*Second and First Class Board of Trade Examinations.*) By John W. Angles. Pp. xxvii + 162. (London: Longmans, Green, and Co., 1919.) Price 5s. net.

(4) *School Mechanics. Part* 1. *School Statics.* By W. G. Borchardt. (Without answers.) Pp. viii + 266. (London: Rivingtons, 1919.) Price 6s.

(1) THIS text-book by three American authors is best described as an elementary mathematical *mélange.* It ranges over a variety of topics, but does not deal explicitly with the calculus, though the fundamental process of the latter is used. Great pains have obviously been expended on the compilation, but it can scarcely be described as an inspiring volume, and is not likely to find favour in British schools and colleges. The authors state in the preface that they desire to emphasise the fact that mathematics cannot be artificially divided into compartments with separate labels, and that they aim at showing the essential unity, harmony, and interplay between the two great fields into which mathematics may properly be divided—namely, analysis and geometry. It is to be feared that those who are to become competent mathematicians must continue to study the subject in compartments, carrying on, of course, several sections simultaneously, leaving familiarity and time to show the inter-relationship. None but the finished scholar can fully appreciate and realise the intertwining of the branches. Only those who reach the hill-tops see the harmony of the landscape and the trend of the watercourses. There are several interesting diagrams and historical references, and also a number of good examples. The volume is well got up and printed.

(2) Mr. Mayo's well-printed and finished book is meant for beginners, for general use in schools, to be within the capacity of the average boy, and also to meet the first requirements of those who intend to specialise in mathematics. That the book will realise all these aspirations is unlikely. So early as p. 6 it presents the beginner with the expression $\underset{x\to 1}{Lt} \frac{x^2-1}{x-1} = 2$, and discusses arithmetical approximations and negligible quantities. The introduction to the subject is of that kind which always leaves the student with the uneasy feeling that the calculus is not quite all right, and gives results just a little out. It is the belief and experience of the reviewer that the opening pedagogics of the calculus must be simple and not over-refined. The easy processes of finding the gradients of chords of curves of the system $y = x^n$ and of deducing therefrom the gradients of the tangents are about all that the average boy can grapple with for a considerable time. The notation can be explained concurrently, and a few easy steps lead on to simple integration and easy applications. Geometry and intuition must be relied on to give the start. The philosophy of the limit is beyond the ordinary pupil. From the school point of view the book covers a fairly wide range, including triple integrals, singular points, partial differentiation, and differential equations. There are many good examples in it, derived from geometry, physics, mechanics, etc., all likely to stimulate a smart boy. In fact, it will probably succeed much better as a second than as a first course.

(3) This is a book on mensuration intended for the use of engineering students of various kinds, as, for example, marine engineers preparing for the First and Second Class Board of Trade Examinations and for the Extra First Class Examination. It deals in a thorough way with the ordinary elementary areas and volumes, such as those of the rectangle, circle, ellipse, sphere, cone, and cuboid, refers to the planimeter, explains Simpson's Rule, and discusses valves, specific gravity, flow of water, etc. It includes also some calculus and the theorems of Pappus. There is an abundance of good examples in the book, both worked and to be worked, so that any student who goes through it conscientiously should conclude his examinations successfully.

(4) Mr. Borchardt's book is part 1 of a School Mechanics, and deals with statics. It is intended for the use of pupils preparing for the higher mathematics, for entrance to Woolwich and Sandhurst, and for the Senior Cambridge Local Examination. The matter is arranged under the following heads, according to the sequence given: the lever, the parallelogram of forces, friction, work and machines, centres of gravity, couples, and general equilibrium. Then follow laboratory problems and test papers. There are plenty of illustrative examples in the text, and a copious supply for the exercise of the student, mostly of a numerical type. If the treatment of the subject presents no fresh or original features, the book is one which can safely be used. J. M.

Our Bookshelf.

The Romantic Roussillon: In the French Pyrenees. By Isabel Savory. Pp. xii + 214 + xxvi plates by M. Landseer Mackenzie. (London: T. Fisher Unwin, Ltd., 1919). Price 25s. net.

THE author of this excellently printed work will not mind our saying at the outset that one of its chief charms is the series of pencil drawings by

M. Landseer Mackenzie. In architecture they give exactly what the trained eye would have us see; in landscape, as in "The Harbour at Collioure," an exquisite sense of atmosphere is conveyed—and, unfortunately, this is the only landscape in the book. The travellers had no high aim in art, history, or geography. They went to this inlet of the eastern Pyrenees because it appeared romantic at a distance. They found it less romantic, but full of charm, the charm that is rarely absent in provincial France. They wandered on foot, and made a spirited ascent of Canigou; but their real interest lay in the old-world villages, the hospitable reception at inns that treat the visitor as a friend, and the general air of remoteness in a land where Catalan is common speech. In history the Roussillon has had no special voice as to whether it should belong to France or Spain. To-day it may well be proud that its lot has lain with France. Was not Marshal Joffre, *le grand-père,* born at Rivesaltes, where the wind blows in across a great lagoon upon the frontier, a relic of the Pliocene sea that once stretched up among the hills? From Roussillon also came Commandant Raynal, the hero of the Fort de Vaux at Verdun, and many a stout defender of the northern lines.

The author, however, is not concerned with such modernities. We gather that her pleasant pilgrimage was made before the war turned all minds to other fields in France; but now the land lies once more open to adventure, and conditions of travel, as we are assured by high authority, are already settling down on their old attractive lines. Naturalists are also artists, and they may well practise their art among the eastern spurs of the Pyrenees. G. A. J. C.

The Journal of the Institute of Metals. Vol. xxii. No. 2. 1919. Edited by G. Shaw Scott. Pp. xii+428+31 plates. (London: The Institute of Metals, 1919.) Price 31*s.* 6*d.* net.

The new volume of this journal opens with a report of the May lecture delivered by Prof. Soddy dealing with the subject of radio-activity. The remainder consists of the papers read at the Sheffield meeting of the institute. Of these the most discussed was one by Dr. Hatfield and Capt. Thirkell on season-cracking, in which a different view is taken from that recently put forward by Rosenhain and Archbutt, and experiments are made to determine the intensity of the internal stress in the case of cold-worked brass. The conclusion is drawn that such stresses approach very closely to the maximum stress which the material is capable of resisting. The mercury salt method has been found very useful for revealing the presence of internal stress. Some very remarkable alloys are described by Dr. Stead. Alloys of tin, antimony, and arsenic, within certain limits of composition, have the habit of forming spherical segments of striking regularity. Dr. L. J. Spencer gives a summary of the information as to the occurrence of strongly curved crystals in minerals, but no satisfactory explanation has yet been given of the conditions under which such curved growth takes place.

The second report to the Beilby Committee on the solidification of metals describes the isolation of crystal grains from certain metals, and a comparison of their form with that of foam cells, the facts pointing to the importance of the share taken by surface tension in determining the grain boundaries. The remaining papers deal with the early history of electro-plating, the properties of standard silver, and the structure of bearing metal, Britannia metal, nickel silver, and duralumin, and the characteristics of moulding sands for non-ferrous work. C. H. D.

Applied Botany. By G. S. M. Ellis. Pp. viii+248. (London: Hodder and Stoughton, 1919.) Price 4*s.* 6*d.* net.

This book is one of a "New Teaching Series" of which the publishers state: "The Series has been written by Teachers possessing valuable practical experience and gifted with the inspiration of the hour's occasion." The "secrets of plant life" are said to be "the substance of this extraordinarily interesting volume." On p. 84 the author informs us that "clover is liable to clover-sickness. Turnips suffer from the finger-and-toe disease. These diseases are caused by bacteria"; and later we learn that Desmids and Conjugate Plants are without chlorophyll. Treating of the enemies of plants, the author writes: "Bacteria turn the living tissue to a slimy and often smelling pulp. The effect is very similar to decay." The problems of potato blight have apparently been solved, for we are told that the hyphæ "penetrate the stem and reach the tubers," and "during the winter resting spores of the fungus remain in the ground and attack the next season's crop." Wart disease is a simple matter, infected soil merely being "treated with sulphur and gas lime." Potato-leaf curl is still due to *Macrosporium solani*, and winter rot to *Nectria solani*.

These are but a few of the "secrets of plant life" which are "the substance of this extraordinarily interesting volume." In addition, however, there are many sentences such as the following: "Free-swimming plants, like Chlamydomonas, must have water in which to swim"; and it is with a sorrowful interest that we read: "Very attractive and useful work may be done by studying the development of fruit, and how the seed is in the end successfully disseminated. The student who undertakes this kind of inquiry becomes at last a worthy biologist." The rest of us must learn to bear our cross with resignation.

W. B. Brierley.

Rückläufige Differenzierung und Entwicklung. By Adolf Cohen-Kysper. Pp. 85. (Leipzig: Johann Ambrosius Barth, 1918.) Price 3 marks.

This book is a further attempt to reduce all life phenomena to mechanical principles. It announces an "ontogenetic law" worded as follows: "The part returns to a phase from which the whole is developed anew."

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Knowledge and Power.

THE question raised in the leading article on "Knowledge and Power" in NATURE of March 25 is of great interest and importance. It is nothing more nor less than the question of using experience as a guide to action, which is the whole purpose of education. The suggestion that its solution requires a fundamental change in the organisation of the Civil Services in order that the best advantage may be obtained for the country from the special knowledge and training of the expert brings to a focus the essential difficulty of the subject. I suppose that the real function of any Department of the Services, civil or military, is to carry out the policy of the Government as formulated or approved by the responsible Minister; and the staff of the Department is recruited in such a way as to secure that object. The knowledge in the light of which the Minister's policy is formed is another matter. It may be taken for granted that if it is well advised, the Government will utilise all the best technical knowledge available. A Minister may find it in special sections of his own Department, or he may try to acquire it from outside. No doubt he is largely guided by his chief permanent officers, and they in turn must use their own knowledge and that of their subordinates or obtain what they can get from outside. How effectively to provide a Minister with all the pertinent experience about technical problems is not an easy question. It is made still harder by the fact that even for experts the recognition of the value of new knowledge is not necessarily automatic. The reception that was given to Thomas Young's theory of light is a reminder for all time that new ideas require favourable environment for assimilation. Consequently, some knowledge of what the world is made of is necessary for all executive authorities. But that, as Kipling says, is another story.

Suppose we picture to ourselves the difference between a youth's progress in the Civil Service and in the career of an expert in science. The Civil Servant is selected by open competition in subjects which may include literature or science; but from the time of his joining the Service the pursuit of either ceases to be a part of his working life, though either may be followed as a hobby. He must leave even his political opinions at home and begin to learn the art of giving expression to the policy of the Department which he joins. He learns from his immediate superiors how things are done. Why they are done does not concern him. He learns also the discipline of a public office and the art of formulating documents for his superior to sign. His opportunity is to make himself so loyal and so efficient in carrying out the policy that any chance of promotion that comes his way is not lost. If he has lofty ambitions beyond his own steps in the Service, he must postpone them until he reaches a position in which he can gain the Minister's ear. Up to that time his life is a life of self-effacement.

The history of the expert is altogether different. His training leads him to begin his career in research, and if he is successful he attains the unspeakable satisfaction of having discovered for himself something of real importance. Thereafter he has always ideas of his own which he strives to realise, and as his experience grows he forms lines of policy for himself, and is not very tolerant of others. His career is one of continuous self-assertion from the beginning. He may derive his ideas from instruction or inspiration, but the expression of them is his own; and what may be only the natural expression of his genius may look like disloyalty to his superiors in the world of red tape.

The positions of the two types with regard to finance are equally diverse. The Civil Servant has no difficulty in establishing the position that as the Minister wants things done he will, of course, be prepared to provide adequate remuneration for those who carry out his wishes. Money is therefore forthcoming. But the expert has to convince the Minister, or persuade someone else to do so, that his projects are worth trying in the public interest and can be justified in Parliament. He has to ask for permission and facilities for research, the results of which are, *ex hypothesi*, unknown; to ask for pay in addition is to invite refusal of everything.

Moreover, the discipline of a body of experts is quite different from that of a public office. What is wanted from an expert is his own spontaneous opinion as a guide to action—a something which a Civil Servant is not expected to possess. It seems to follow that experts and Civil Servants are as different as oil and vinegar, and the endeavour to mix them promiscuously in one organisation will not work. They belong to different atmospheres; what stifles one gives buoyancy to the other.

Somehow or other an advisory side for formulating policy ought to be organised on different lines from those of the administrative side which carries out the policy. But if there is a separate organisation on the technical side it ought to have direct access to the Minister finally responsible, and not be fenced off from him by a secretariat trained on different lines. There are sure to be misunderstandings and ultimate despair if all the work of a professional technical staff has to pass upwards and downwards through the refracting and distorting medium of an inexpert secretariat. The scheme of organisation must be in sectors reaching continuously from the Ministerial centre to the circle of recruitment. The technical staff itself will want the assistance of "civil servants" content to follow out the policy which is indicated. The mischief begins when the Civil Service forms a complete belt in the inner regions of the organisation. In that case an inexpert Minister is completely surrounded by inexpert advisers, and then power is cut off from knowledge.

F.O.I.

THE vast conflagration of the late war rendered conspicuous many truths that were little suspected by the majority, and not the least of these was the importance, the necessity, of organised and accurate scientific knowledge and research for national success. Unfortunately, this is already in danger of being forgotten while we are engaged in the strenuous task of preserving for our country its due and fitting place in the industries and activities of the world, and the leading article in NATURE of March 25 has sounded a very necessary note of warning. It rightly emphasises the need that the ultimate administrative authority should be vested in men with technical knowledge and experience, and not in Civil Service officials appointed originally, for the most part, on the basis of purely literary attainments. This authority will, however, never be conceded to the man of science until the scale of his remuneration corresponds to the importance of his work. It was repeatedly

demonstrated during the war that scientific men who from motives of patriotism accepted a low scale of salary for their services in Government Departments were accorded an equally modest official status.

The ultimate basis on which an adequate recognition of the importance of the scientific technical expert must rest will be the estimation in which science and scientific research are held by the great mass of intelligent men and women. It must be realised, in the first place, that a training in science on the right lines and under the right men will be as efficient in broadening the outlook on the world and stimulating the imagination of the student as a detailed study of the vicissitudes of ancient wars or the eccentricities of Greek and Latin irregular verbs. It must also be recognised that no course of science can be considered complete unless it has included a session at least spent in scientific research, humble though it may be and directed by more experienced workers. But it must be genuine research, not merely a "heuristic" imitation of the real thing.

The more science graduates who have learnt to understand what research means there are scattered about the country—in factories, in counting-houses, in Government offices, in educational establishments of every kind, and, most important of all, in municipalities and legislative bodies—the wider will be the recognition of the value of science.

Unfortunately, scientific studies are seriously handicapped in the competition for university students by the fact that the fees are, as a rule, distinctly higher than those for arts. There is, therefore, a strong pecuniary inducement for parents to select an arts rather than a science curriculum for their children. Such a handicap is obviously opposed to the national interest, and should not be allowed to continue.

In view of the urgent reasons for associating research with higher scientific education, it is to be regretted that the general tendency of Government policy should be to divorce industrial research from the universities and to place it in the hands of associations of commercial firms. The discoveries that open up new lines of development in great manufacturing industries are arrived at by processes essentially similar to those that lead to advances in pure science, and if we are to get the best results it will be by the co-operation of the vigorous university life which has sprung up in recent years at so many centres in busy industrial districts with the commercial enterprise in its vicinity.

Finally, if we are to secure to science its full weight in the councils and policy of the country, we must not confine our propaganda to the "governing" or upper classes, or to the ranks of professional workers, or to those engaged in commercial pursuits, but we must develop by all the means in our power a love of science in the great army of the manual operatives, whom it would seem that in a not distant future we shall, willingly or unwillingly, have to acknowledge as our masters. With their increased leisure there should be no difficulty in enlisting a large contingent of men and women who will be interested in science, either for its own sake or for its value in enabling them to understand the meaning of the work in which they are engaged. Some of them will in all probability definitely embrace a scientific career, and in this they should receive every assistance and encouragement, while others will render no less service as amateurs and as missionaries of science among their fellows. Already, I am told, a great deal is being done in this direction in connection with University College, Nottingham, and no doubt much is being accomplished on similar lines at the Midland and Northern universities. At present the operations of the Workers' Educational Association are largely confined to the somewhat restricted domains of constitutional law and history and political economy, but a few years may see a great development of more stimulating and attractive studies in the broad realms of science.

March 31. JOHN W. EVANS.

The Secondary Spectrum of Hydrogen.

THE recent investigation by Dr. Merton of the effect of an admixture of helium on the intensity distribution in the hydrogen spectrum appears to have given a very strong clue towards the elucidation of that spectrum. On the photographs taken by Dr. Merton (reproduced in part in Proc. Roy. Soc., October, 1919) the spectra appear completely different in the cases of pure hydrogen and of hydrogen mixed with helium. Many lines, in the first case quite strong, are totally absent in the second; others remain practically unaltered in intensity; while a third set appears in the second case, though practically or completely invisible in the first. Such results seem, at first sight, to point to the existence of at least three classes of lines which are mutually independent, one class being unaffected by helium and the others affected in opposite senses.

A somewhat exhaustive investigation which I have made recently in regard to these photographs, kindly lent to me by Dr. Merton, and the previously published tables of the spectrum has convinced me, however, that this interpretation is not the correct one. It was known already that the secondary spectrum of hydrogen contained two sets of lines, one showing, and the other not showing, the Zeeman effect. A third and doubtful set were abnormal in regard to the Zeeman effect. Dufour examined many of the strong lines in the spectrum, and, although his investigation needs still to be extended much further, a considerable amount of exact knowledge of individual lines is available.

Fulcher also had previously investigated the low-potential discharge in hydrogen, and isolated two band spectra peculiar to this discharge, which spectra we may call the Fulcher bands. They differ from more ordinary bands in their large component separations, and their most important part is in each case a set of triplets which recur towards the red end. Although they do not readily fit the Deslandres type of formula, I have been able to establish a mathematical relationship between the two bands, from which it appears that they must be considered jointly as one band. In addition to the triplets there are many associated sets of single lines, which Fulcher considered, on experimental grounds, to belong to the same band system.

Dr. Merton's results have made a valuable contribution which enables us to isolate these Fulcher bands completely from the rest of the spectrum.

The conclusions at which I have already arrived may be summarised as follows:—

The secondary spectrum of hydrogen consists of a set of band spectra—how far divided into sets which are mutually independent in the mathematical sense is uncertain, but at least partially so divided—together with a superposed spectrum of single lines. The band lines are those which show no Zeeman effect, and the lines of the superposed spectrum all show the Zeeman effect. This general statement still requires considerable experimental work to establish its complete truth, but the evidence so far available is sufficient to leave little doubt in the matter.

Dr. Merton's spectra, taken in the presence of helium, preserve what I have called the superposed

spectrum without much change of intensity, and it is undoubtedly due, on all grounds, to a different atomic or molecular mechanism from that producing the bands. This superposed spectrum exhibits very pronounced "constant frequency difference" effects, and there is good reason to believe that sets of series spectra of the ordinary Rydberg type may be included in it and form the basis of the constant differences of wave-number. The series spectra of hydrogen would then be no longer confined to the Balmer series.

On the photographs the behaviour of the "band" lines is peculiar. The "head"—a word not used in the ordinary sense, but as denoting the strongest line of the band and the one most remote from the red end—is preserved in intensity in helium, or even enhanced, while all the other members disappear. A line in pure hydrogen may be weak, but if it is really a band-head in this sense, it is prominent in the presence of helium—the head is not always the strongest line in a band in pure hydrogen. This consideration is the real clue to the interpretation of the photographs, and it has been found possible to isolate the entire Fulcher band, which is of a remarkable structure and accounts for the great majority of lines between H_α and H_β, in part of which region the previous measures have been very incomplete and misleading. Other strong bands of similar character occur in other regions, and it is already clear that the complete analysis involves only a few such individual bands showing no Zeeman effect, together with a line spectrum showing Zeeman effect, and apparently capable of arrangement in constant frequency differences.

These investigations will shortly be published, but in view of the importance this spectrum has now assumed in relation to atomic structure a preliminary statement of its nature appears to be desirable.

J. W. NICHOLSON.

University of London, King's College,
March 21.

International Council for Fishery Investigations.

A PERUSAL of the programme of the International Council for Fishery Investigations, as outlined in NATURE of March 18, substantiates the criticisms published in 1902 and 1903, as well as later. In the interests of the fisheries and of the public in these critical times it is imperative to direct attention once more to the position. In the original programme of about twenty years ago the Council were to discover whether the yield of the sea-fisheries was increasing or diminishing, and especially to demonstrate the impoverishment of the sea (as if the myriads of ova on the fishmongers' slabs every year afforded no lesson); to show to what extent fishing-grounds could be depleted without danger; to point out what fishing apparatus was destructive; to investigate the small fish grounds; to make discoveries of practical importance to the fisheries; to publish annual results; and finally to produce data (even within two years) on which British and foreign legislation could be based.

Now, after sixteen to twenty years' labour and a great expenditure of public money (for salaries went on during the war), it is found that the impoverishment plea is dropped, along with most of the heads just mentioned as requiring solution. The new scheme, to take the heads in the order in which they appear (see NATURE, March 18, p. 84), includes an inquiry into the result of "the most gigantic scientific experiment ever made in respect to the closure of areas." It is unlikely that the fisheries of the North Sea will be to any extent altered by the partial closure caused through the operations of the Grand Fleet. The ways of Nature are not so simple. Then comes the old phantom of the diminishing plaice and the protection of the race by a size-limit, an impracticable idea so far as the security of the younger plaice goes. The larval, post-larval, and smaller forms are in prodigious numbers, and are safe. Nor is confidence in the Council increased when the ten years' work of the Scottish Fishery Board's ship, *Garland*, in the closed areas is now regarded as ineffective, and the subject not sufficiently studied! In other words, the deliberate conclusions of the Scottish Board, so resolutely upheld, and on which the closure of the Moray Firth and other areas was based, are null and void. That is one way of escaping from an untenable position. The Council may well spare the "intensive study" of the plaice so far as the prosperity of the British fisheries is concerned, and so with further experiments on plaice-marking and drift-bottles, as well as on the food of the young. Nothing important on these heads can result from continued expenditure. The lemon-dab requires little attention, for, like other doomed fishes of the kind, it has re-asserted itself. There is no urgent need for studies on the herring, though this was supposed to be one of the diminishing fishes not long ago. Yet a word must be said in favour of the Danish exploration of the North Atlantic, where, and in the Mediterranean, Dr. Johs. Schmidt carried out such excellent work on the life-history of the eel.

The hydrographical and plankton work of the Council has hitherto borne little fruit in the matter of the fisheries, and it is unlikely that, after twenty years' probation, more will be accomplished.

The revival of the bathybius-myth in the form of the supposed "vitamines" in sea-water may give point to a sentence, thus: "The searcher for economic results in fisheries must have the basal theory and knowledge . . . as the foundation on which he has to build," but that is *vox et praeterea nihil* unless a practical acquaintance with the whole details of the life-history of the sea-fishes is possessed by him. Mere collation of statistics without such a check is of little avail in the complex problem of the sea-fisheries, which, however, now as heretofore, hold their own against the combined attacks of their own kind, as well as of man, seals, whales, birds, and invertebrates. Marine animals have been kept in pure sea water without food for years, yet the suggested application of the "vitamine" theory to the oyster and mussel does not offer much scope. The best *parcs* for fattening the oysters have much more than "vitamines," and even the *ejectamenta*, etc., of the mussels in the estuaries will by and by raise mounds several feet above sea-level.

Four French names are given as members of the Council, but they are less familiar than those of Fabre-Domergue, Canu, Cligny, Raveret-Wattel, and Pellegrin. Again, one British name is conspicuous by its absence, viz. that of Dr. A. T. Masterman, a highly trained and talented fisheries expert. It is to be hoped that no interference by officialdom, as dealt with in the leading article in NATURE of March 25, is connected with his retirement. Those who remember the case of Sir Joseph Hooker and Mr. Ayrton have reason to be jealous of the official status of experienced men of science in carrying out their researches for the benefit of the country.

Finally, there can be little doubt that Britain would be better and more economically served by competent workers in its marine laboratories, where, moreover, young zoologists could acquire a competent knowledge of the marine fisheries.

W. C. MCINTOSH.

The Plumage Bill and Bird Protection.

THE protection of beautiful and interesting birds is the object of Col. Yate's and Lord Aberdeen's Bill now before Parliament. The chief end is to close Great Britain (and presumably all parts of the British Empire controlled from London) as a market in which the plumage of wild birds (excepting eider down and ostrich feathers) may be bought and sold. The reasons for excepting the down of the eider duck and the plumes of the ostrich need scarcely be explained. The eider duck strips herself of the downy feathers she develops during the breeding season and lines her nest with them. This down can be obtained without injuring the bird, or even without depriving her nestlings, who leave the downy nest soon after birth. Such a large proportion of ostrich plumes is obtained from tame birds (and the wild ostrich chicks are so easily domesticated) that it is scarcely worth while pursuing the wild bird for its feathers. Moreover, the plumes can be removed from the tame birds painlessly.

The Bill is drawn so as to protect wild birds from persecution by closing to the trade in their feathers the very important British market, which, together with the strong action of the United States and Canada, will go far towards extirpating this commerce. We should protect beautiful, useful, interesting, and harmless birds—adjectives which include all the avian class except, perhaps, the house-sparrow, the tree-sparrow, and the wood-pigeon, because:—

(1) They are beautiful in shape, in plumage, in their manner of life, or in their voice, and they always add to the æsthetic charm of a landscape.

(2) The majority of birds feed upon insects, ticks, land mollusca, small rodents, or carrion. They are our principal allies in keeping the insect hosts at bay and destroying the sources and disseminators of germs which breed disease in man, beast, and plant. They save our food crops and our timber-trees from destruction by insects, snails, and slugs; they attack snakes; and they assist to maintain the balance of creation in favour of man.

(3) Sea-birds—especially gulls, auks, petrels, gannets, frigate-birds, cormorants, and penguins—are the producers of guano useful in agriculture and horticulture.

(4) Many fruit-eating birds are great distributors of the seeds, stones, and nuts of valuable timber-trees or trees producing spices, dyes, drugs, or fruits of value to humanity.

Ergo, all birds, save the sparrows and the European wood-pigeon (which is very destructive to crops, and is believed to spread the germs of diphtheria), should be protected from attacks which are not necessitated by some real human need. What would be such a need? The preservation of the bulk of a food crop, or the necessity for the bird's flesh, or the requiring of its under-plumage as a material for warding off cold. The last-named requirement does not affect the tropics or sub-tropics. Most insect-eating or guano-producing birds are unfit for food, and are disliked from that point of view by the savage quite as much as by the white man. Penguins and a few other sea-birds yield a valuable oil, but there is no reason why penguin rookeries should not be established for that purpose provided the species is properly preserved from serious diminution. Yet the amount of oil thus obtained is trifling in comparison with the yield from whales, porpoises, seals, and fish; and these inhabitants of the seas and oceans are more protected by their habitat from devastating attacks than are birds resorting to a terrestrial life during the breeding season. At any rate, the extermination of marine mammals or of fish is not such a loss to landscape beauty or to the economics of human life as is the destruction of sea-birds.

What is the offset against this argument for wild-bird preservation? What quality do beautiful and interesting wild birds possess that they should be attacked, pursued, and destroyed until in many cases they become extinct? They produce feathers and plumes of great beauty in colour or of exquisite outline or texture which are desired as a personal adornment by certain European—not Asiatic, American, or African—women, who stick these trophies in head-coverings or as a trimming on their corsage. There is also in about half a dozen instances a further use of wild birds' plumage in the making of artificial flies used by anglers.

All that European women or anglers can in reason require in the way of plumes, wings, tails, or skins of birds for their decoration or other purposes can be obtained without cruelty from the domesticated or preserved birds that are killed for food or kept for egg production—ostriches, the domestic fowl in a hundred varieties, the common pheasant and other pheasants bred in aviaries, pea-fowl, turkeys, guinea-fowl, pigeons, grouse, partridges, ducks, geese, certain kinds of wild duck sufficiently preserved to be in no danger of dying out, and so forth. Trade in such feathers is in no way restricted by the Plumage Bill. It is not right that rare and beautiful or exceedingly useful wild birds of the tropics and sub-tropics should be destroyed, eliminated from the landscapes for the sole purpose of decorating the persons of European women. We are told that the disuse of this practice would throw out of employment four or five thousand persons in England, France, and Holland; but surely they could find work in dealing with the feathers of domesticated birds. H. H. JOHNSTON.

St. John's Priory, Poling, Arundel.

IT is desirable in a discussion on the Plumage Bill to ensure that knowledge is not controlled by sentiment, and that the solid facts of the matter are borne definitely in mind. Supporters of the Bill give three main reasons for it. They claim that the Bill will stop (1) the extinction of rare birds; (2) cruelty in that it will stop the killing of breeding birds, and so preserve their young; and (3) cruelty in the actual slaughter of birds at all. Against the Bill are the statements that it effects nothing in regard to these points (in that it has no action in the places where the birds occur); that it stops a great deal of perfectly harmless and legitimate trade; and that the real protection of birds must be an international matter, which was being quite easily brought about by voluntary effort, which effort will be killed by the Bill.

The important points are to consider (1) whether there is cruelty, (2) whether birds are being made extinct owing to the plumage trade, (3) whether the present Bill will prevent cruelty and extinction, and (4) whether any alternative proposal can be suggested. In regard to cruelty, it is extremely difficult to secure real evidence apart from unsupported statements. In a letter to the *Times* a few days ago Mr. H. J. Massingham produced a private letter detailing horrible cruelty in China with getting egret plumage. There is an American bulletin that details the killing of 150,000 or 300,000 "albatrosses and noddies." One may admit the first as "cruelty," but scarcely the second so long as hunting and shooting are carried on in England. The Right Hon. Sir C. E. H. Hobhouse in the House of Commons referred to an auction of 75,000 herons, and to another of 77,000 herons, 22,000 crowned pigeons, 25,000 humming-birds, and 162,000 Smyrnian kingfishers. But is this wrong? No one could say that this trade was making any bird extinct.

The trade wants them in thousands, and would not seek a bird so rare that it was available only in hundreds.

I think there is no evidence of any bird being made extinct by acts of the plumage dealers, whose interest lies in birds being abundant, but the Bill allows the scientific collector to bring in the rarest plumage. In this connection some persons emphasise the destruction of insectivorous birds as being a pity; but an insectivorous bird may itself destroy beneficial insects—say, dragon-flies, which themselves feed on mosquitoes.

Mr. C. W. Mason and I have published a very careful analysis of the food of birds in India, and we decided that herons were injurious (see Memoirs of the Agricultural Department of India, vol. iii., 1911). I have before me three such memoirs, all by entomologists, relating to England, Australia, and India; and it is necessary to distinguish very clearly what the value of a bird is. Apart from this, no one interested in Nature could desire the extinction of any species of bird or other life at all, and we need not restrict our precautions solely to beneficial birds.

The third point is whether the proposed Bill will protect the birds. It will not, because it simply prohibits importation into England of all plumage except ostrich and eider down, unless it is worn or is personal property. The plumage goes just the same to Paris, and no bird is protected at all. The same amount of plumage will come to England, only it will be all made up in Paris.

The fourth point is: What can be offered in its place? I suggest the Bill should prohibit the import of scheduled birds, and that if evidence is brought of cruelty or of approaching extinction, the importation of the bird from that locality should be prohibited by simply adding it and its locality to the schedule. There might well be a Standing Committee attached to the Board of Trade to hear representations and to vary the schedule.

The egret is greatly mentioned. It is said to be destroyed for its plumes while the young birds are still helpless in the nest; but I have photographs of an egret farm in Sind, and there are hundreds of such farms. The egrets' plumes are taken without cruelty, and the birds are not killed. Why, then, indiscriminately forbid egret plumes and destroy an industry in India? Why not exclude Chinese egret, and represent the matter to the Chinese Government? Why bar also the possibilities of farming emu, rhea, marabou, lyre-birds, pheasants, etc.?

The Committee for the Economic Preservation of Birds up to August, 1914, endeavoured to put this matter right. It is a fact that this Committee had secured the co-operation of the plumage trade of Paris, Vienna, Berlin, and London, and that the whole trade voluntarily stopped the import and use of the plumage of a number of birds which were thought to be in danger of extinction or to be beneficial. This was the only effort to secure the real remedy, international co-operation; and the present Bill completely wipes out that possibility.

Perhaps the present discussion will produce the solid evidence (apart from opinion) on which the supporters of the Bill rest; up to the present there has been little other than sentiment.

One last point that has a scientific bearing is that the Bill allows the importation of plumage for scientific purposes and for museums. The scientific collector specialises on rarities which the museums need, and it is exactly this type of collector who needs to be stopped; but the Plumage Bill is backed precisely by the ornithologists who want rare skins, and so can get them.

I think the Bill needs a great deal of reconsideration, that a reasonable Bill can be drafted which will protect birds, and that the present one allows for the collection of the nearly extinct birds and does nothing to protect the cases where there is cruelty.

H. M. LEFROY.

IF I were still in Parliament I should give as cordial support to the Importation of Plumage (Prohibition) Bill as I would have done to the late Lord Avebury's Bill had I been in the House of Lords when he introduced it. But I recognise that if the measure is to receive support from men of science, it must be based mainly on scientific rather than on humanitarian or sentimental grounds.

I notice that Prof. H. M. Lefroy, in a recent letter to the *Times*, seems to assume that the advocates of prohibition are actuated by sentiment only. He asks whether they consider it less cruel to kill spring chickens for their flesh than pretty birds for their plumage. If this is meant for argument, it seems particularly feeble, unless the whole question of the ethics of consuming animal food is to be raised. If it were as easy to rear egrets, birds of paradise, rifle-birds, etc., for the sake of their plumage as it is to rear cattle, sheep, and domestic fowls for their flesh, probably none but extreme humanitarians would raise serious objections, even if the birds had to be killed, which is not necessary in ostrich-farming. From a scientific point of view, the matter seems to resolve itself into the question whether the extinction or drastic reduction of the most beautifully clad birds can be viewed with indifference. I cannot speak at first hand about the extent to which reduction has been carried, but the evidence on this subject has proved sufficient to convince the Legislature of the United States that restriction of the plumage trade was necessary if some of the choicest species were to be saved from extinction.

I cannot but hold the conviction that the true functions of naturalists are not limited to the mere work of collecting, recording, and classifying, and that it is incumbent upon them to aid in resistance to the extermination of such existing species as do not interfere with the welfare of human beings. But, after all, I can claim no higher standing than that of a field-naturalist, setting more store on a bird in the bush than two in a glass case or on a lady's hat!

HERBERT MAXWELL.

Monreith.

THE subject of the Importation of Plumage (Prohibition) Bill now before Parliament is one in which all zoologists, and, indeed, all lovers of Nature, should take a lively interest. It seems almost certain that much cruelty is involved in the operations of plume-hunters, and it is difficult to see how it could be otherwise, especially when the plumes are collected during the breeding season. This question, however, I leave to others who have the necessary evidence at hand, together with the important problem of the part played by the birds in the destruction of noxious insects.

The point I wish to emphasise is the irreparable loss, not only to science, but also to mankind in general, which will result from the extermination of many of the most interesting and beautiful creatures that exist. Unfortunately, there appears to be no limit to the lust of personal gain. Were it possible to pluck a star from the heavens and sell it for the decoration of a lady's headdress, star-hunters would doubtless be as active as plume-hunters in destroying man's rich inheritance.

It is clearly our duty to preserve for future generations, as well as for our own enjoyment and edifica-

tion, the wonderful products of Nature by which we are still surrounded. The destruction of a work of art would be condemned as vandalism by all educated people, and it is difficult to believe that any intelligent woman would willingly be a party to the destruction of some of Nature's finest masterpieces. It has taken many millions of years to produce a humming-bird or a bird of paradise, and what work of art can compare with these living gems? Their destruction, once accomplished, would be irrevocable, and future generations of zoologists, with all their science of genetics, might strive in vain to produce anything to replace them.

Should such wantonness be permitted merely to satisfy the greed and vanity of a few human beings? I think not, and therefore I hope the Plumage Bill now before Parliament will be passed, and that other nations will follow our example in endeavouring to put a stop to a practice which is a dark blot on civilisation.

Possibly an even more hopeful method of accomplishing this aim would be by the formation of women's societies for the express purpose of discountenancing the fashion of wearing plumage derived from wild birds, except in the case of those the destruction of which is demanded for other and sufficient reasons. Such societies might do much useful work in enlightening the ignorant and thoughtless and in fostering a wholesome public opinion. Possibly they exist already; if so, now is their opportunity.

ARTHUR DENDY.

The Magnetic Storm of March 22–23 and Associated Phenomena.

THE magnetic storm of March 22–23 was one of the most considerable recorded at Eskdalemuir during the last nine years throughout which continuous records have been obtained. It began with the abrupt disturbance known as a "sudden commencement" at 9h. 12m. G.M.T. on March 22, the rapidity of the change in the horizontal components at that time being so great that the photographic impression of the moving light-spot was too faint to enable its details to be traced. The main features, however, began to develop immediately afterwards. On the traces recording the changes in declination and the westerly component there were no very large motions in the interval between the sudden commencement and 14½h., but there occurred the intense agitation due to oscillations of short period. At the same time the northerly component of force gradually rose, having superposed upon it several large, slow motions as well as numerous short-period oscillations.

The larger motions of both horizontal components began soon after 16h., and by 17h. the declination trace had passed beyond the edge of the recording sheet. At this time, when the extreme westerly declination was reached, its value must have been at least 1° 43′ beyond its undisturbed value. The north component trace was similarly off the sheet upwards (*i.e.* with increased value) from 16h. to 20h. From 20h. until midnight the disturbance in the horizontal field was on a lesser scale, but during the four hours after 0h. 30m. there occurred a series of large and rapid oscillations. For example, in six minutes from 1h. 20m. to 1h. 26m. the declination shifted eastwards through 2½°. The northerly component fell rapidly in value after midnight, and the trace was off the sheet downwards several times between 0h. and 4h. The total range of this component must, therefore, have exceeded 700γ—an unusually high value. From 4h. to 10h. on March 23 the motions were smaller, but extremely rapid, the period averaging about four minutes. After 10h. no further considerable disturbance occurred, but a notable sudden change, in a direction north-east-downwards, took place with its maximum at 19h. 17m.

The vertical force magnetogram for the storm is of more than usual interest. So far as this component is concerned, the ordinary course of events during a magnetic storm which begins before midnight includes a gradual increase in downwards force towards a maximum which is reached before midnight, followed by a fall for an hour or more; then a check, followed by a further fall, and a gradual recovery to nearly normal value, which may be reached about 8h. In the present case four prominent maxima are shown before midnight—at 14h. 27m., 17h. 24m., 20h. 10m., and 23h. 49m. The range of disturbance between the second and highest maximum and the second minimum (at 19h. 6m.) was 565γ. Soon after midnight there occurred an extremely rapid fall in value which sent the trace off the sheet for nearly six hours. The subsequent recovery was characterised by well-marked pulsations the period of which was irregular, but averaged about five minutes, and were of unusually large amplitude. The occurrence of these pulsations in vertical force *at the end* of a storm is a feature requiring attention in any theory attempting to explain magnetic storms.

The disturbance was accompanied by an auroral display, including the "curtain" form at a considerable altitude, and extending, at 0h. 50m. on March 23, to within 30° of the southern horizon. There was little cloud at the time, but low mist made observation of details difficult.

Science and the New Army.

NATURE of March 25 publishes a leading article "Knowledge and Power," a letter from Col. E. H. Hills, and a paragraph in the "University and Educational Intelligence," all dealing with related subjects. A sentence in the last-named paragraph throws light on the other communications. It reads: "Every officer in command of a company will be held responsible for the instruction of his men." The paragraph neglects to state, however, that the majority of these officers entered Sandhurst or Woolwich at an immature age, probably without competition, and are almost as ignorant as the men whose education they are to supervise.

During the war the lack of scientific knowledge and of habits of exact thought of these officers was shown not only by their persistent attempts to prevent the use of scientific means, but also by their childlike faith in a formula or parrot-cry. "Follow the barrage," "Counter-attack," "Defence in depth," are some that come to mind—formulæ passed down through the official channels to be applied without thought to all possible situations.

In this country war is still looked upon as an art, whereas it is rapidly becoming an exact science.

The firing of millions of projectiles, involving an enormous expenditure of energy, not only in lives, but, what counts almost as much in the long run, also of labour, is a matter for exact calculation if the maximum probable results are to be obtained. At the present time such problems are solved by intuitive methods, and will be so whilst the present system of officering the Army obtains.

All hope of any real progress must be abandoned until a change is made; then, perhaps, we shall no longer see directors of research absolutely ignorant of the problems that are being solved or await solution.

An Electronic Theory of Isomerism.

I HAVE read with considerable interest the suggestion of Dr. H. S. Allen in NATURE for March 18 that the Langmuir atom could be applied with advantage to the study of organic compounds. Dr. Allen is, however, doubtful if the "cubical atom" of Langmuir will explain the existence of isomerides of the type of the three malic acids, the glutaconic acids, the cinnamic acids, α-, β-, and γ-sugars, etc.; and it is certainly difficult to give formulæ for the triple linkage on the cubical atom. These difficulties disappear with the Bohr atom (NATURE, February 19, p. 661) and the modification of the Langmuir atom proposed by Major A. E. Oxley (*ibid.*, March 25, p. 105). With both theories *n* and *s* valencies are obtained, and, so far as a qualitative examination of valency in organic chemistry is concerned, it is difficult to decide between the two models. Major Oxley has, however, shown that his theory can give an adequate explanation of the magnetic properties of organic compounds, and equal success may be obtained with a theory of optical activity.

The crucial test appears to lie in the calculation of the optical activity of substances in the crystal form, for it is probable that in the liquid condition a large number of isomeric forms exist.

The alterations in optical activity which occur with change of solvent and the phenomena of mutarotation and of racemisation appear to be connected with changes in the direction of rotation of electrons. These changes could, perhaps, be more easily explained by the small orbital motions demanded by the Langmuir theory than by the larger orbital motions in the theory of Bohr. W. E. GARNER.

University College, London.

IN view of Dr. A. E. Oxley's remarks in NATURE of March 25, I should like to point out that the object of my letter was to inquire whether the supposition of stationary electrons is essential to Langmuir's theory. Langmuir himself expressed the hope that it would be possible to reconcile his theory with that of Bohr, "which has had such marked success in explaining, and even in predicting, new facts." I ventured to suggest that electrons revolving round the nucleus could form stable groups as required by Langmuir without needing to be stationary.

The difficulty of explaining diamagnetism on the theory of the astronomical atom is well known. Possibly the difficulty may disappear when the nucleus is better understood. If electrons are considered as point-charges, the supposition that they revolve in very small orbits without any constraining force seems arbitrary. Dr. Allen's theory of ring electrons is preferable, and undoubtedly removes certain difficulties. It appears, however, that to account for spectral lines the diameter of the orbits must be comparable with that of the atom, which implies that the electrons revolve round the nucleus.

Since the structure of the atom is still uncertain, would it not be preferable to avoid, if possible, in a chemical theory a statement as to the immobility of the electrons? S. C. BRADFORD.

Science Museum, South Kensington, S.W.7.

Percussion-Figures.

C. V. RAMAN describes in NATURE of October 9, 1919, percussion figures in isotropic solids. These figures are known in geology, and are found on rounded boulders of compact, homogeneous rocks, such as flint and quartzite. Albert Heim[1] described in 1871 the "percussion-cones" (Schlagconus) brought forth artificially on pieces of flint by a powerful short blow with a hammer. F. Mühlberg,[2] of Aarau (Switzerland) was perhaps the first geologist who described the percussion-figures (Schlagfiguren) on rounded boulders (1885). On some of the quartz-boulders from the River Aar, near Aarau, he found from hundreds to thousands of circular cracks, which he explained by the abrasion of boulders which formerly received coniform cracks through the numerous impacts during their transport through the river-bed.

These percussion-figures must be intersecting figures of cones and the surface of the boulder, and, therefore, will form, on sufficiently great boulders, nearly circles, ellipses, and parabolas. Mühlberg described thus percussion-figures arising from torrent-action, whereas A. Bigot[3] (1907) emphasised that the "figures de percussion" arise from wave-action. He noticed them on the beaches of Basse-Normandie, particularly on quartzite boulders. Finally, P. N. Peach[4] (1912) gave a very fine picture of the "bulbs of percussion" found on a rounded stone (chalk flint) dredged by the *Michel Sars* about 230 miles south-west of Mizen Head, Ireland. He pointed out that these figures indicate that "the stones had originally been dashed against each other by torrent- or wave-action."

Besides the term above-mentioned, Peach also uses the term "chatter marks," which seems to me less commendable, because this expression is also used by T. C. Chamberlin[5] for a special type of glacial striæ on the rock-bed. These curved figures were also described by Hagenbach in 1883, and afterwards called "arcs de Hagenbach" by L. Rollier.[6]

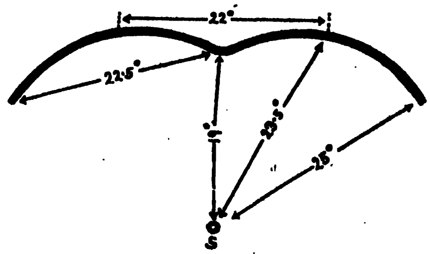
A Peculiar Halo.

ON March 16 I observed a peculiar halo here; its form is best shown by a rough sketch. The angles were taken with a pocket slide-rule held at arm's length, and are, therefore, only approximations, but the relative values are probably fairly correct. The halo was brightest at the point above the sun, and faded off somewhat on each side; it ended rather abruptly at the points shown in the sketch. The



colours, with red nearest the sun, were not very pure, but they were purer in the arms than in the centre. The phenomenon was visible from 14.45 to 15.40, with intervals of disappearance when a sheet of alto-stratus became so thick that nothing could be seen through it but the glare of the sun. It was not possible to see any higher layer of cloud, but the halo probably had its origin in a layer of cirro-stratus. The measurements were taken at 15.40; a few minutes later the halo disappeared for the last time. C. J. P. CAVE.

Sherwood, Newton St. Cyres, Devon, March 20.

Sea-birds: Their Relation to the Fisheries and Agriculture.

By Dr. Walter E. Collinge.

During the past few years there has been a growing opinion on the part of the general public and those connected with our fisheries that the enormous number of sea-birds on our coasts are inimical to the fisheries and to a less extent to agriculture. This view has been fostered to a large degree by the public expression of irresponsible statements and by the fact that we do not possess any exact and trustworthy knowledge of the nature of the food of these birds. Even amongst ornithologists and other students of wild-bird life widely divergent views are held.

Hitherto no investigation sufficiently comprehensive has been made, and in those cases where the birds of a restricted area have been studied, or where an insufficient number of specimens has been examined, the results have proved inconclusive, and, owing to the methods employed, to some extent misleading.

About two and a half years ago, under the auspices of the Carnegie Trust for the Universities of Scotland, an investigation was commenced in which it was proposed to examine large series of each species from numerous localities during each month of the year, and to estimate the food by the volumetric method. Although this research is not yet complete, sufficient data are in hand to warrant an expression of opinion upon this subject, and it is felt that such is highly desirable at the present time, when so many erroneous views are being circulated.

Up to the present, fourteen species have been examined, represented by upwards of three thousand specimens. The species are cormorant, shag, common gull, herring gull, great black-backed gull, lesser black-backed gull, black-headed gull, kittiwake, common tern, razorbill, guillemot, little auk, puffin, and great northern diver. Whilst it is not possible here to reproduce the numerous percentage tables showing the nature of the food for each species during the various months of the year, or those illustrating the seasonal variations or the percentages of the different species of fish destroyed, it is possible to make a general statement which we believe future work will more fully amplify and confirm.

First, we would point out that the importance and amount of fish that has been generally regarded as forming the diet of most of these birds are not borne out by an actual examination of their crop and stomach contents. Fish does not (with such exceptions mentioned later) constitute the bulk of their food or anything like the major portion of it. Indeed, one has only to watch carefully such species as the black-backed gull, the herring gull, and the lesser black-backed gull on the shore after the ebb of the tide to realise how essentially these birds are the scavengers of the shore. If they turn landwards, then injurious insects, earthworms, frogs, and carrion are greedily fed upon. Further, if one confines one's observations to birds drowned in the fishermen's nets, entirely misleading ideas are obtained, for these few birds constitute but the merest fraction of the huge bird population frequenting our coasts.

The above-mentioned fourteen species may be divided into three classes, viz.: (i) Purely fish feeders; (ii) largely fish feeders, but most of the fish are not utilised by man as food; (iii) fish feeders to less than 20 per cent. of the total bulk of their food. Most of the species fall into class (iii). In class (i) is placed the cormorant and shag, for, so far as observations go, their food consists entirely of fish, and chiefly of food fishes. In class (ii) is placed the common tern. The remaining eleven species must all be placed in class (iii).

From information obtained from various sources, there is a general consensus of opinion that the cormorant and the shag do an enormous amount of harm to the fisheries. Nothing can be advanced in their favour, though it is open to question whether our fish supply would show any increase even were these birds exterminated. Respecting the common tern, sand eels constitute fully 50 per cent. of its fish diet; the gunnel or butter fish, gobies, young gurnard, herring, and haddock are also taken.

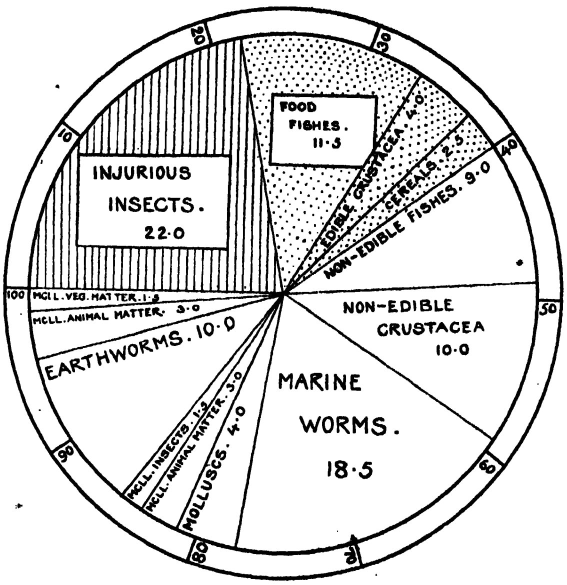
It is not possible here to give the details of the analyses for all the remaining species; we shall therefore select one, the black-headed gull. More than five hundred specimens of this species have been examined, obtained from various localities and during each month of the year. This species is selected because it has increased enormously during the last twenty years, and is now generally regarded as one of the most injurious both to the fisheries and to agriculture.

Of the total bulk of food consumed in a year, 96 per cent. consists of animal matter, and 4 per cent. of vegetable matter. Of the former the actual amount of food fishes found was 11·5 per cent., and of other fishes (not utilised by man as food) 9 per cent., or a total fish diet of 20·5 per cent. Edible crustacea are present to the extent of 4 per cent., and other forms, non-edible, to that of 10 per cent. Marine worms constitute 18·5 per cent., molluscs 4 per cent., echinoderms 2·5 per cent., injurious insects 22 per cent., other insects 1·5 per cent., earthworms 10 per cent., and miscellaneous animal matter 3 per cent. Of the vegetable matter, 2·5 per cent. consists of cereals, and 1·5 per cent. of miscellaneous matter (Fig. 1).

If the huge bulk of food from which these figures have been obtained means anything at all, it indicates clearly and definitely that this species is a highly beneficial one. By no reasonable deduction can it be shown to be otherwise, for nearly two-thirds of its food is of a neutral nature, viz. 60 per cent. (38 per cent. of which consists of shore refuse.) Only 18 per cent. is injurious, and 22 per cent. is highly beneficial. We

feel certain that no one who has had experience in work of this character will for a moment question whether this percentage of food, which is conferring a benefit upon agriculture, balances the injury that is inflicted upon an inexhaustible and ever-increasing fish supply.

Very similar figures might be advanced for the remaining species, none of which are taking more than 20 per cent. of fish per annum of their total bulk of food. Is the sea so impoverished that we cannot afford these birds this amount of fish-food in exchange for their beneficial action in destroying more than 20 per cent. of injurious insects (of which 7·2 per cent. consist of wireworms in the case of the black-headed gull)?



G. 1.—Diagrammatic representation of the percentage of food of the black-headed gull. The portions shaded by longitudinal lines represent food that it is beneficial the birds should eat; those stippled, food that it is injurious they should eat, and the blank portions food of a neutral

The records, both individually and collectively, show that the bulk of the food of these birds is not fish, but animal matter of a neutral nature. Of course, if one classes all annelids, non-edible crustacea, and molluscs as fish food, then very different figures may be obtained; but those who are acquainted with the abundance and the nature of the marine life cast up on the shore will agree with us in regarding these as a neutral factor.

If the figures are summarised for all the species in class (iii) (so far as our investigation has gone), the verdict is certainly in favour of these birds. It is very easy to condemn a species because at some particular season of the year or in some district a certain number have been found to be feeding upon food fishes; but, as has been frequently pointed out, such partial records do not give a true estimate of the food as a whole. It must not for one moment be thought that we are endeavouring to explain away the injuries inflicted, but we contend that it is unfair to judge any species of wild bird upon a local or partial record; the nature of the food generally throughout the United Kingdom and over the whole year is what we have endeavoured to learn.

Very interesting results have been obtained as to the seasonal changes of food and the variations in different localities. Sex and age also influence the quantity of food taken, and although the figures are yet incomplete, they point to the fact that the males take a larger quantity of food than the females, and the young birds more than the old.

It is not within the province of this inquiry to discuss the question of the impoverishment of the sea, but it will be impossible to conclude it without taking cognisance of the leading views on the subject and their bearing upon this question.

Finally, all the work goes to show that with a few exceptions—*e.g.* the cormorant and the shag—the food of each species is partly beneficial, and, even if for the moment we admit that the percentage of the fish destroyed is an injury, we must take into consideration the benefits derived by reason of the nature of the remaining food. This varies in different seasons of the year and according to the nature of the locality, but if an average is taken of the eleven species in class (iii), we find that the total percentage of injuries is less than that of the benefits, and that the bulk of the food is of a neutral nature.

It is obvious that, after examining upwards of three thousand specimens, with the results obtained, the question of the food of our commoner sea-birds and their effect upon the fisheries and agriculture can no longer remain where it was; and, whilst not advocating any special protection, except in one or two cases, any agitation for their destruction cannot be condemned too forcibly, for, altogether apart from sentimental reasons, it is extremely unlikely that our fisheries would benefit or show any marked improvement, even were hundreds of thousands of these birds destroyed annually, whilst agriculture would certainly be the sufferer by such a loss.

The Imperial College of Science and Technology.

The Chancellor of the Exchequer, speaking in the House of Commons on March 16, expressed concern at the extraordinary expansion of business in the promotion of companies, and said he was convinced that the time had come when part of the money thus called for only creates increased competition for the limited supplies of labour and material which are all that are available. Few of us can doubt that this concern of the Chancellor is more than justified, but it is not only for purely industrial enterprise that appeals to the public at large are being made daily for large sums of money. Owing to the universal rise in prices, educational institutions

find themselves seriously handicapped in their endeavours to fulfil the functions assigned to them. In the case of such educational institutions as the schools and colleges maintained wholly, or almost wholly, from rates and taxes, the solution is less difficult, and may be found in an increased education rate combined with an increased Government grant. For the universities which have to depend largely upon fees and endowment, and can rely only partly on Government grants, the difficulties created are very serious. It should, however, be borne in mind that money expended on education is one of the most productive forms of national expenditure, and, whatever may be the dangers of the inflation of industrial capital, the nation is not yet within remote danger of educational inflation. Rather is it suffering grievous detriment from the semi-starvation of its higher educational institutions.

Among the higher educational institutions which are in need of financial help, the Imperial College of Science and Technology holds a prominent place, and an appeal issued some months ago by the governing body makes clear the magnitude and urgency of this want. The Imperial College of Science and Technology was incorporated under Royal Charter in July, 1907, and was established "to give the highest specialised instruction and to provide the fullest equipment for the most advanced training and research in various branches of science, especially in its application to industry." The governing body was also required to carry on the work of the Royal College of Science, the Royal School of Mines, and the City and Guilds (Engineering) College, institutions previously existing, but which in 1907 became associated as integral parts of the new institution.

The Imperial College is thus an association or federation of colleges, deliberately charged by the terms of its charter to afford facilities for the highest work in pure and applied science, especially in its application to industry. As an indication of the magnitude of its work, it may be noted that in the year 1907–8 there were 665 students, including 20 engaged on post-graduate work, and the annual expenditure on maintenance approximated to 50,000*l.* In the year 1913–14—the year before the war—the number of students was 943, including 185 engaged on post-graduate work, and the annual expenditure on maintenance approximated to 90,000*l.* During the war the numbers of students were reduced by about two-thirds, but in May last year there were 841, including 110 post-graduates, and as the numbers are rapidly increasing there is every indication that the college will soon be busier than ever before. On the basis only of the pre-war annual expenditure, the Imperial College is as large as Manchester University, larger than Liverpool University, and twice as large as Bristol University. Its rank in science and technology, whether viewed from the range and standard of its teaching and research, or from its equipment, is at least as high as that of any existing university in Great Britain.

In order that the college may rise to the height of its responsibilities and fulfil the functions assigned to it by its charter, the governing body estimates that for new buildings and equipment at least 600,000*l.* is required, and for the adequate development of the work of the college a further annual income approximating to 100,000*l.* The capitalised value of the total additional requirement has been put in round figures at more than 2,000,000*l.* It is large, but much less than the amount required for a modern battleship, and is not incommensurate with the importance to the nation and the Empire of the work which the college has to do.

From a quarter to one-fifth of the total number of students are carrying on original investigations under the direction of their respective professors, and this, together with the research work of the staff, results in considerable additions to knowledge annually. The investigations range over a wide area of science, especially in its application to industry. The contributions thus made to increased industrial efficiency are no mean factor in the national development and prosperity. At the same time, in the course of these investigations the relevant researches in pure science are not neglected, and thus much is done continually to widen the bounds of knowledge as knowledge.

The teaching work carried on in the college may be divided into (*a*) associateship and (*b*) post-associateship. The former consists of courses, approximately of honours graduate standard, leading respectively to associateships of the Royal College of Science (A.R.C.S.), the Royal School of Mines (A.R.S.M.), and the City and Guilds Institute (A.C.G.I.); and the latter of courses of study and of research, comparable in standard with M.Sc. and D.Sc. work, leading to the diploma of membership of the Imperial College (D.I.C.).

Styled "Imperial" from the first, the college has constantly to bear in mind the growing industrial needs not only of the Kingdom, but also of the Empire, and to do this it must possess a flexibility and an adaptability suitable to the ever-changing conditions of industry. To take one example, the war disclosed, as in a flash, the perilous condition of the optical glass and optical instrument industry in this country through the dependence for many years on foreign supplies, particularly from Germany. A new department of technical optics has been established by the governors of the Imperial College, which, by research, by the supply of trained technologists in this field, and by the education of the users of optical instruments, must go far to second the efforts of the manufacturers to build up and stabilise this important and essential national industry. At no time was the need for an intensive and extensive development of science, both pure and applied, more needed than at the present time of national reconstruction after five

years of a devastating world war, and in this task of extending our knowledge of pure science and its application to the whole field of industry the Imperial College is called upon to play a vital and predominant part.

The recognition of how great and important are the responsibilities thus cast upon the Imperial College has led to a movement for obtaining for the college the status of a university with the power to confer degrees in its own subjects or faculties. The movement is backed by the unanimous support of the rector and professors of the Imperial College, and it is supported, so far as can be ascertained in any organised way, by the overwhelming majority of the past and present students of the college. The issue raises, no doubt, questions that are novel and complicated in relation to university education in general and to the University of London in particular. Nothing but good can come from a free and frank examination of the proposition in all its bearings, undisturbed and unprejudiced by lesser interests than that of increasing the efficiency of university education and especially of scientific education.

Magnetic Disturbances and Geological Structure.[1]

THE research described in the report before us was undertaken at the instigation of the Iron Ores Committee of the Conjoint Board of Scientific Societies. Certain lines and centres of magnetic disturbance had been noted in Britain so long ago as 1890 by Rücker and Thorpe, and a new magnetic survey by Mr. G. W. Walker in the years 1914 and 1915 confirmed the existence of these disturbed areas. It is well known that iron is the only element which gives rise to magnetic effects of considerable intensity, and it was therefore of importance to determine whether any relationship could be established between the location of these disturbances and the distribution of iron ores.

The detailed magnetic survey of (1) the proved sheet of iron ore, mainly in the state of ferrous carbonate, round Irthlingborough, and (2) the known areas of magnetic disturbance about Melton Mowbray, was therefore undertaken by Mr. Walker. At the same time, Dr. Cox reviewed the geology of the areas and collected specimens of rocks which promised to afford evidence in the matter, while the magnetic susceptibilities of these materials were determined by Prof. Ernest Wilson.

The results of the magnetic and petrological examination of the rocks confirm the opinion that the magnetic susceptibility of rocks depends scarcely at all upon the percentage of metallic iron they contain, but upon the condition—*i.e.* state of oxidation—of that iron; and that, although rocks composed of ferrous compounds show higher susceptibilities than those constituted of fully oxidised ferric compounds, only those rocks in which the iron occurs as the mineral magnetite have notable magnetic susceptibility. It was shown that parts of the granite of Mount Sorrel have a susceptibility more than four times as great as that of the most magnetic of the local Jurassic iron ores, and ten to fifteen times as great as certain basic igneous rocks, which, though high in iron, contain no appreciable amount of magnetite.

Another point of some interest is the variability of magnetic properties shown by samples taken from one continuous rock mass. The outer part of the dolerite sill proved in the Owthorpe borehole was a fine-grained rock having a glassy base; its iron ore occurs as magnetite, and the magnetic susceptibility of the specimen examined was 472×10^{-5} C.G.S. units. The coarse-grained rock from the centre of the intrusion, however, in which the iron ores crystallised as ilmenite, gave a susceptibility of only $10{\cdot}3 \times 10^{-5}$ C.G.S. units. A like low susceptibility was noted also in the basalt from the Southwell borehole.

The magnetic phenomena of the Irthlingborough district are adequately explained by the presence of such a large, flat-lying sheet of feebly magnetic rock as the Bajocian iron-ore bed, but in the Melton Mowbray district the proved limits of the marlstone iron-ore bed bear no relation to the observed magnetic phenomena. Moreover, the consideration of the magnetic irregularities obtained in the Melton Mowbray district shows that the source of the disturbance cannot be less than 3000 ft., and may be as much as 10,000 ft. beneath the surface. The only rocks in this region which have the requisite magnetic susceptibility and may be expected to occur at these depths are dolerites, such as are found intrusive into the Coal Measures throughout the Midland coalfield area, or possibly granites like those which have invaded the old pre-Carboniferous rocks in Charnwood Forest.

Mr. Walker's observations show that, near to Melton Mowbray, there are two main magnetic disturbances, and that the line joining them ranges north of west and south of east from Melton Mowbray towards Rempstone, passing a little south of the latter place. This line agrees with that of a known fault of small throw which cuts the Mesozoic rocks, and may be expected to have a much larger throw in the Palæozoic and older strata underground. Similar magnetic disturbances are noted near certain large faults in the Nottingham district. Rücker and Thorpe showed that magnetic disturbances are always to be expected where a sill or dyke of highly susceptible rock is displaced by a fault, and that, if any rock containing magnetite is intruded as a dyke among non-susceptible rocks, similar magnetic disturbances must occur. It is known that in many districts the place of intrusions has been determined by faulting, and it is pointed out by Dr. Cox that the concealed coalfield of Notting-

[1] "A Report on Magnetic Disturbances in Northamptonshire and Leicestershire and their Relations to the Geological Structure." By Dr. A. H. Cox. Phil. Trans. Roy. Soc., Series A, vol. ccxix., pp. 73–135; plates Ap. i.–Ap. iii.

hamshire should end off at an anticline, probably faulted, in the region about Melton Mowbray. Such an anticline has an east-and-west trend, and carries round the strike of the Coal Measures from its general north-east-and-south-west to an east-and-west direction. The Rempstone-Melton Mowbray magnetic disturbances, therefore, are interpreted as additional evidence of the existence of a fault which in the underlying Palæozoic rocks may have a considerable throw; and it is regarded as probable that a sill of dolerite is displaced by this fault, or that an irregular mass of dolerite is intruded along it.

The hope is expressed by the author that a like method of attack may prove to be of use as a guide to the divining of the position of faults beneath a cover of unconformable strata in other districts—*e.g.* in concealed coalfields, where dolerites or other rocks containing a high proportion of magnetite are present. Unfortunately, however, or fortunately from the point of view of the coal miner, dolerites are not an invariable concomitant of coal seams, and it therefore follows that the use of the method in determining the limits of concealed coalfields would appear to be somewhat restricted.

British Crop Production.[1]

By DR. EDWARD J. RUSSELL, F.R.S.

CROP production in Britain is carried on in the hope of gain, and thus differs fundamentally from gardening, which is commonly practised without regard to profit and loss accounts. Many poets from times of old down to our own days have sung of the pleasures to be derived from gardening. But only once in the history of literature have the pleasures of farming been sung, and that was nearly two thousand years ago.

Ah! too fortunate the husbandmen, did they but know it, on whom, far from the clash of arms, earth their most just mistress lavishes from the soil a plenteous subsistence.—"Georgics," Bk. II., i., 458 *et seq.*

"Did they but know it"! Even then there seem to have been worries!

This seeking for profit imposes an important condition on British agriculture: maximum production must be secured at the minimum of cost. This condition is best fulfilled by utilising to the full all the natural advantages and obviating so far as possible all the natural disadvantages of the farm—in other words, by growing crops specially adapted to the local conditions, and avoiding any not particularly well suited to them.

From the scientific point of view the problem thus becomes a study in adaptation, and we shall find a considerable interplay of factors, inasmuch as both natural conditions and crop can be somewhat altered so as the better to suit each other.

It is not my province to discuss the methods by which plant-breeders alter plants; it is sufficient to know that this can be done within limits which no one would yet attempt to define. The natural conditions are determined broadly by climate and by soil. The climate may be regarded as uncontrollable. "What can't be cured must be endured." The scheme of crop production must, therefore, be adapted to the climate, and especially to the rainfall.

The rainfall map shows that the eastern half of England is, on the whole, drier than the western half. In agricultural experience, wheat flourishes best in dry conditions and grass in wet conditions; the vegetation maps show that wheat tends to be grown in the eastern and grass in the western part. The strict relationship is that seed production is appropriate to the drier, and leaf production to the wetter, districts.

The great soil belts of England south of the Trent run in a south-westerly direction; north of the Trent, however, they run north and south. A heavy soil, like a wet climate, favours grass production; a light soil, like a dry climate, is suitable for arable crops. The great influence of climate is modified, but not overridden, by the soil factor.

The arable farmer grows three kinds of crops: corn, clover or seeds hay, and fodder crops for his animals or potatoes for human beings. The same general principles underlie all, and as corn crops are of the most general interest (though not necessarily of the greatest importance), they will serve to illustrate all the points it is necessary to bring out. We have seen that wheat is cultivated more in the eastern than in the western portion of the country. The figures for consumption and production are as follows:

Millions of Tons per Annum.

	Consumption in United Kingdom	Production in England and Wales			Production in United Kingdom		
		Before war 1914	1918	1919	Before war 1914	1918	1919
Wheat ..	7·40	1·6	2·3	1·8	1·7	2 6	2·0
Barley ...	1 96	1·2	1·2	1·1	1·6	1·5	1·3
Oats ...	4 30	1·4	2·0	1·6	3·0	4·5	4·2

During the war very serious attention was paid to the problem of reducing the gap between consumption and production. A working solution was found by lowering the milling standard, retaining more of the offal, and introducing other cereals and potatoes; a very considerable proportion of the resulting bread was thus produced at home. But the war-bread did not commend itself, and disappeared soon after the armistice; since then the consumption of wheat has gone up, and the divergence between consumption and production has again become marked. There is no hope of reducing consumption; we must, therefore, increase production. Additional production may be obtained in two ways: by increasing the yield per acre, and by increasing the number of acres devoted to the crop.

The yield per acre is shown in the following table:—

Measured Bushels per Acre.[2]

	(1908–17) Average yield per acre			
	England and Wales	Scotland	A good farmer expects	Highest recorded yield
Wheat ...	31·0	39·9	40 to 50	96
Barley ...	31·9	35·4	40 to 60	80
Oats ...	39·3	38·9	60 to 80	121

The average results include bad farmers and bad seasons; the good farmer expects to do considerably

[1] Discourse delivered at the Royal Institution on Friday, February 20.

[2] Unfortunately the terms "bushel" and "quarter" (8 bushels) lack definiteness, being used officially in three different senses and unofficially in several others also. The following are some of the definitions of a bushel:—

	Official Statistics. A definite volume having the following average weight lb.	Corn Returns Act. Volume occupied by following weight lb.	Grain Prices Order. Volume occupied by following weight lb.	Frequent Practice. Volume occupied by following weight lb.
Wheat ...	61·9	60	63	63
Barley ...	53·7	50	55	56
Oats ...	39·3	39	42	42

better, but he has many things in his favour: superior knowledge, greater command of capital, and possession of good land; he will, therefore, always stand above the average. Even his results can be improved; the highest recorded yields show what can be done with present varieties and present methods in exceptionally favourable circumstances. The figures give the measure of the scientific problem, which is to discover what changes would be necessary in order to bridge the enormous gap between the average and the best. In three directions progress is possible; we may modify the plant or the soil, or we may mitigate the effects of unfavourable climate.

Before the soil can be brought into cultivation at all it is necessary to carry out certain major operations—draining, enclosing, etc.—which have to be maintained in full order. These lie outside our present discussion; we must assume that they are properly carried out, which is by no means always the case. Given adequate drainage, soil conditions are profoundly modified by cultivation, which has developed into a fine art in England and Scotland, and is, indeed, far better practised here than in most other countries. But it is an art, and not yet a science; the husbandman achieves the results, but no one can yet state in exact terms precisely what has happened. A beginning has been made, and a laboratory for the study of soil physics has been instituted at Rothamsted and placed under Mr. B. A. Keen, where we hope gradually to develop a science of cultivation. For the present cultivation remains an art, and, further, it is essentially a modern art. The medieval implements, as shown in the Tiberius MS. (eleventh century) and the Luttrell Psalter (fourteenth century), were crude, and left the ground in an exceedingly rough condition. Great advances were made throughout the nineteenth century. Robert Ransome, of Ipswich, took out his first patent in 1785 to improve the plough; he was followed in 1812 by Howard, of Bedford, and later by Crosskill, Marshall, Rushton, Fowler, and others, who have made British implement-makers famous throughout the world. Given time and sufficient labour, the good British farmer using modern implements can accomplish wonders in the way of cultivation.

Unfortunately, neither time nor labour is always available. Ploughing is possible only under certain weather conditions, and there are many days in our winters when it cannot be carried out. Unless, therefore, a large staff of men and horses is kept, the work often cannot be done in time to allow of sowing under the best conditions.

The early days of the life of a plant play almost as important a part in its subsequent history as they do in the case of a child. Illustrations are only too numerous of the adverse effect of being just too late for good soil conditions. One from our own fields is as follows:—

Work completed	Seed sown	Yield of wheat 1916 Bushels per acre
Just in time	Nov. 24, 1915	26·8
Just too late	Feb. 17, 1916	19·3

The farm-horse will not be speeded up, but maintains an even pace of 2½ miles per hour. According to the old ploughman's song still surviving in our villages, an acre a day is the proper rate:—

We've all ploughed an acre, I'll swear and I'll vow,
For we're all jolly fellows that follow the plough.

But under modern conditions it is impossible to get more than three-quarters of an acre a day ploughed on heavy land, and the scarcity of teams threatened to bring arable husbandry into a hopeless *impasse*. Fortunately for agriculture, the internal-combustion engine appeared on the farm at a critical moment in the shape of the tractor, and has brought the promise of a way out.

The tractor has two important advantages over the horse. First of all, it works more quickly. Its pace is 3½ miles per hour instead of 2½ miles. It turns three furrows at a time instead of one only; on our land it ploughs an acre in four hours instead of taking nearly a day and a half, as required by horses. There is no limit to the work it can do; even an acre an hour is no wild dream, but may yet be accomplished. It therefore enables the farmer to get well forward with his ploughing during the fine weather in late summer and early autumn, and thus to obtain the great advantages of a partial fallow and of freedom to sow at any desired time. On our own land our experience has been as follows:—

Dates of Completion of Sowings of Wheat and Oats.

Year	Wheat	Oats	
1916	February 17	October 16	Horses only
1917	March 16	" 17	Horses only
1918	January 26	" 27	Horses only
1919	November 26	" 5	Tractor

Further, if the plough is correctly designed and properly used, the tractor does the work fully as well as horses—even the horse-ploughman admits that. It therefore increases considerably the efficiency of the labourer, which, as we shall see later on, might advantageously be raised. The cost of working is apparently less, though it is difficult to decide this until one knows what the repairs bill will be. In our case the cost is:—

Cost of Ploughing per Acre, Autumn, 1919.

	By tractor s. d.	By horses s. d.
Labour	7 7	10 2
Maintenance	—	22 6
Oil and petrol	7 8	—
Depreciation and repairs ...	6 3	—
	21 6	32 8
Time taken ...	4 hours	1½ days

The internal-combustion engine is only just at the beginning of its career on the farm, and no one can yet foresee its developments. It is being used at present simply like a horse, and is attached to implements evolved to suit the horse. But it is not a horse; its proper purpose is to cause rotation while it is being used to pull, and in some cases, indeed, this pull is reconverted into rotary motion.

The second great method of improving soil conditions is to add manures and fertilisers. Farmyard manure is more effective than any other single substance; it is likely to remain the most important manure, and if available in sufficient quantity it would generally meet the case. Realising its importance, Lord Elveden generously provided funds for extended investigations at Rothamsted into the conditions to be observed in making and storing it. This work is still going on, and is leading to some highly important developments.

Farmyard manure, however, is not available in sufficient quantities to meet all requirements. The chemist has long since come to the aid of the farmer; he has discovered the precise substances needed for the nutrition of the plant, and prepared them on a large scale. Like cultivation, this is largely a British development; it was in London that the first artificial manure factory was established in 1842, and for many years the industry was centred in this country. The fertilisers now available are as follows:—

Nitrogenous—Nitrate of soda, nitrate of lime, sulphate of ammonia, and cyanamide (nitrolim).

Phosphatic—Superphosphate, basic slag, mineral phosphate, guano, and bones.

Potassic—Sulphate of potash, muriate of potash, and kainit.

Agricultural chemists have worked out the proper combinations for particular crops, and obtained many striking results.

Without using any farmyard manure they have maintained, and even increased, the yield of corn crops, fodder crops, and hay; and in the two latter cases there has been an increase, not only in yield, but also in feeding value per ton. In spite of seventy years' experience there is still much to be learned about the proper use of artificial fertilisers, and they may still bring about even fuller yields from the land.

The yield of corn crops can be increased by artificial fertilisers, but not indefinitely; the limit is set by the strength of the straw. As the plant becomes bigger and bigger, so the strain on the straw increases, until finally, when the plant is some 5 ft. high, it cannot stand up against the wind, but is blown down.

Little is known about the strength of straw. It is a property inherent in the plant itself, and differs in the different varieties. It is affected by the season, being greater in some years than in others. It is affected also by soil conditions. At present the strength of the straw is the wall against which the agricultural improver is pulled up. The problem can undoubtedly be solved, and the plant-breeder and soil-investigator between them may reasonably hope to find the solution.

Another great effect of artificial fertilisers which has not yet been fully exploited is to mitigate the ill-effects of adverse climatic conditions. Phosphates help to counteract the harmful influence of cold, wet weather; potassic fertilisers help the plant in dry conditions. The combination of a suitable variety with an appropriate scheme of manuring is capable of bringing about considerable improvement in crop production.

A demonstration with the oat crop on these lines was arranged last year in a wet moorland district, and the crops when seen in August were as follows:

	Estimated crop Bushels.	
Local variety, local treatment ...	27	Harvest late
„ „ phosphatic manuring	45–54	„ earlier
Special variety "Yielder," phosphatic manuring	54–66	„ earlier, stands up well

The potato crop is governed by the same general principles as corn crops. It furnishes more food per acre than any other crop, but it is much more expensive to produce, and therefore is grown chiefly in districts where the conditions are particularly well suited to it: the Fens, Lincolnshire, the plains of Lancashire, and the Lothians, though smaller quantities are grown in almost every part of the country. The production and consumption are as follows:—

Potatoes: Annual Production and Consumption.

	Production					
	In England and Wales			In United Kingdom		
Consumption	Pre-war 1914	1918	1919	Pre-war 1914	1918	1919
6·5	3·0	4·2	2·7	7·5	9·2	6·3
Millions of acres	0·46	0·63	0·48	1·20	1·51	1·22

We are thus self-supporting in the matter of potatoes. We do, however, import about half a million tons per annum of early and other potatoes; we also export seed potatoes and some for food—in all, about one million tons per annum.

(*To be continued.*)

Notes.

WE regret to announce the death, on April 3, at eighty-four years of age, of Capt. E. W. Creak, C.B., F.R.S., formerly Superintendent of Compasses, Hydrographic Department, Admiralty.

THE following names were inadvertently omitted from the list of Commanders of the Order of the British Empire (C.B.E.) announced in last week's issue of NATURE:—Mr. C. E. Fagan, secretary, British Museum (Natural History); Sir W. H. Hadow, Vice-Chancellor of the University of Sheffield; and Mr. A. R. Hinks, F.R.S., secretary of the Royal Geographical Society.

LORD SUDELEY has given notice of the following motion which he proposes to bring before the House of Lords on April 21:—"To call attention to the decision of his Majesty's Government to discontinue the appointment of an official guide at Kew Royal Botanical Gardens; and to move to resolve, That the Government be requested to carry out at these gardens the system of free popular guide-lectures on the same plan as adopted with marked success in the Government museum and picture galleries of the Metropolis, and to take such further steps as after inquiry may be found desirable for developing the resources of these gardens to the fullest extent in the interests of scientific and popular education, together with the recreation of the public."

THE RIGHT HON. F. D. ACLAND recently asked in the House of Commons whether the Lord President of the Council "is aware that dissatisfaction is being expressed by scientific workers with the appointment of a man without scientific qualifications as director of research to the Glass Research Association; whether, as the Department of Scientific and Industrial Research provides four-fifths of the funds of the association, the Department was consulted before the appointment was made; and does he approve of the appointment as giving a guarantee that State funds devoted to scientific research will be wisely expended?" Mr. Fisher replied to the question, and his answer included the following statements:—(1) The successful candidate has a wide and successful experience of scientific research into the problems of the glass industry, and is considered by the association to be the man best suited for organising and directing the research needed by it. (2) The responsibility for the selection of a director of research rests in each case with the research association concerned, and not with the Department of Scientific and Industrial Research, which has no power to approve or disapprove the appointment of any individual. (3) The Department guarantees three-quarters of the expenditure of the research association up to a certain limit, but payment of the grant is conditional, among other things, on the approval by the Department of the programme of research and of the estimate of expenditure thereon. (4) The Advisory Council of the Department, after considering all the relevant circumstances with great care, recommended the approval of the expenditure involved in this director's appointment.

MR. B. D. PORRITT has been appointed director of research by the Research Association of British Rubber and Tyre Manufacturers.

THE annual meeting of the Iron and Steel Institute will be held at the Institution of Civil Engineers, Westminster, on Thursday and Friday, May 6 and 7, and will be adjourned from May 7 to May 14, when a final session will be held at the Mappin Hall, Sheffield. On the opening day the retiring president, Mr. Eugène Schneider, will induct into the chair the president-elect, Dr. J. E. Stead, the Bessemer gold medal for 1920 will be presented to Mr. Harry Brearley, and the president will deliver his inaugural address. The autumn meeting of the institute will open at Cardiff on September 22.

THE World Trade Club, of San Francisco, which is conducting an active propaganda in favour of the compulsory adoption of the metric system of weights and measures, both in this country and in the United States, has issued under the title "Metric Literature Clues" a list of references to books, pamphlets, documents, and magazine articles on standardisation in terms of metric units. Although far from being a complete bibliography of the metric system, it includes most of the best-known works on the subject, and contains a fairly full list of the publications of the United States Government and of the Bureau of Standards. In some cases the title of a book or article is followed by a brief summary of its contents, sufficient to indicate to those interested in weights and measures whether it is worth while consulting the work in question. This is the most practical and useful publication of the World Trade Club with regard to the metric system that has yet come to our notice.

AT a meeting of the Association of Economic Biologists held on March 24 the following papers were read: (1) Mr. D. W. Cutler, "The Relation of Protozoa to Soil Problems"; (2) Mr. J. F. Martley, "The Resin-Galls of the Wood of the Sitka Spruce (*Picea sitchensis*)"; (3) Dr. W. Lawrence Balls, "The Nature and Scope of Botanical Research in the Cotton Industry"; (4) Dr. M. C. Rayner, "The Calcifuge Habit in Ling (*Calluna vulgaris*) and other Ericaceous Plants"; (5) Dr. H. Wormald, "Shoot Wilt of Plum Trees." Perhaps the outstanding feature of the meeting, emphasised alike in papers and discussion, was the necessity of pure research as a basis for all economic applications of biology. Not only is it impossible to conduct investigations into any applied aspect of a biological problem in which at the same time equal attention is not given to the more fundamental considerations, but more usually it is also not possible to separate the economic from the pure issues. A further point of importance, arising particularly in the discussion on Dr. Balls's paper, is the great shortage in this country of young botanists competent to undertake research on industrial problems. With the expected development of research associations and the partial recognition by manufacturers of the vital place of the botanist in industry, this factor will become increasingly apparent and be a serious menace to progress.

THE Port Erin Biological Station will be occupied during the Easter vacation (March 20 to April 20) by nine or ten professors, each with a group of senior students, including Profs. Doncaster, Harvey-Gibson, Johnstone, and Herdman (Liverpool), Prof. Gamble (Birmingham), Dr. Tattersall (Manchester), Mr. Douglas Laurie (Aberystwyth), Prof. Benjamin Moore (London), Prof. Cole (Reading), Prof. Stephenson (Lahore), and Prof. Dakin (Western Australia). There are also groups of other post-graduate workers and senior students from Cambridge, Nottingham, Liverpool, and other centres, as well as a large botany class in the earlier part of the vacation, to be followed by a zoology class later. The laboratory accommodation is strained to the utmost capacity, and additions to both building and staff are urgently required. The usual excursions for shore-collecting and plankton work and dredging are being arranged, and the fish-hatching is in full swing. The season is an early one at sea. The phyto-plankton has consisted for the last ten days of March mainly of Coscinodiscus and Biddulphia, and the plaice in the spawning-pond have produced fertilised eggs at least a month earlier than usual—the first hatched larvæ were noticed on February 9—and herring are being caught each night in the bay. The Bill transferring the biological station and fish hatchery from the Manx Government to the Oceanography Department of the University of Liverpool has now passed through the House of Keys, and the University takes over the control of the institution and the work as from April 1 last. The director wishes it to be known that this makes no change in the use of the biological station by researchers from other universities.

THE Ministry of Agriculture and Fisheries last year purchased an estate of more than 1500 acres of typical heath-land at Methwold, in Norfolk. This estate is to be a National Demonstration Farm, and one of the chief objects for its existence is to show what can be obtained from poor heath-land by the adoption of good husbandry methods. The Weekly Service for March 20 from the Ministry of Agriculture gives a short account of the work to be undertaken at this farm. Two hundred acres of the estate have been reclaimed from bracken land, so that at the present time 1043 acres are under arable cultivation, 43 acres under grass, and 441 acres are waste heath. The chief part of the scheme will be the building up and improvement of the land by chalking and by the addition of organic matter. Tobacco-growing on a comparatively large scale will also be a feature of the cultivation. By encouraging the growing of this crop the Ministry hope to supplement the experimental work carried out during the past six years by the British Tobacco Growers' Society, Ltd., and also to assist those smallholders in the neighbourhood who may be inclined to try tobacco-growing when there is a central station at hand to supply the necessary information and to provide for the treatment of the crop. The scheme also includes stock-rearing, poultry-keeping, and pig breeding and rearing on the open-air system. The result should prove very valuable both for large-scale farmers and for smallholders, since the

fields are of a good size and well adapted to the use of implements of a large, up-to-date form, while the light and early character of the land should render it specially suitable for small arable dairy holdings.

THE revival of Oriental research is happily marked by the reappearance of Prof. Flinders Petrie's admirable journal, *Ancient Egypt*. Great changes have occurred since the outbreak of hostilities. In Egypt the main actors are gone—Sir Gaston Maspero, his son Jean Maspero, Legrain, and Barsanti. On the English side the losses have been equally severe—Sir A. Ruffer, H. Thompson, I. Dixon, and K. T. Frost, all victims of the war; and at home the early death of Prof. Leonard King has left history and archæology crippled. But, so far as was possible, work has gone on, particularly under the new conditions in Palestine, where a school of archæology, under the superintendence of Prof. Garstang, is being founded. The British School in Egypt is starting work with a large staff, and in the United States, under Prof. Breasted, the Oriental Institute of the Chicago University has been opened. But funds are badly wanted both in Egypt and in Palestine, and though this is an unfavourable time for such an appeal, there is good hope that British archæologists will provide the necessary assistance.

IN the *Museum Journal* (vol. x., No. 3, September, 1919) Mr. H. V. Hall discusses the question of African art. So much has been said, Mr. Hall remarks, about the uniformity of African culture that the variety which exists tends sometimes to be overlooked. The people of eastern and southern Africa are chiefly interested in the products of the animal, those of central and western Africa in the products of the vegetable, kingdom. Speaking broadly, the region east of the lakes and south of the Zambezi-Congo watershed is the home of pastoral tribes, and the Congo and the Lower Niger races practise agriculture. Hence the latter have more leisure to devote to art-work. The question of foreign influence on the negro is of great importance. There are at least four routes from the north and north-west by which the dark heart of the continent can be reached. A growing mass of evidence points to the conclusion that, even in historic times, these routes have never been quite barred to civilising influences; especially in the expansion of old Egypt the solution of many problems of culture apparently indigenous in Central Africa must be sought.

A COMMITTEE appointed by the Royal Anthropological Institute is engaged in collecting information regarding megalithic monuments. As an example of the scientific method of conducting such a survey, Messrs. J. S. Wilson and G. A. Garfitt, in the March issue of *Man*, supply a map of the Eyam Moor circle in Derbyshire. This work is important in connection with Sir Norman Lockyer's investigations. "In the survey of the Eyam Moor circle several large stones were noted on the near horizon towards the N.E. and E. The path of the sun at sunrise for the latitude of the circle, after making allowances for refraction, was calculated for different declinations of the sun and plotted on the chart. It will be seen that the position of prominent stones plotted on the diagram appears to mark the position of sunrise at midsummer and at the equinox. On the diagram the position of sunrise is shown for the present obliquity of the ecliptic, or sun's apparent declination of 23° 27′, also for an obliquity of 23° 57′, which, according to the estimates of astronomers, would have been correct 2000 years before the Christian era. The small difference in the position of the sun indicates the difficulty of fixing the age of a monument by this means."

THE Department of Agriculture, Federated Malay States, in view of the necessity for an increased local production of foodstuffs, has issued a special Bulletin (No. 30) on "Food Production in Malaya," compiled by Mr. F. G. Spring and Mr. J. N. Milsum. The booklet contains 112 pages and 12 plates, costs one dollar, and brings together a large amount of useful information. It includes sections on seasons and rainfall, types of land (whether coastal or inland), soils, tillage, agricultural machinery, rotation of crops, manures, and insect pests and other diseases. Suitable cereal, pulse, and root crops are described, and their cultivation, harvesting, yield, and economic uses considered in some detail. The principal cereals are ragi (*Eleusine coracana*) and rice; various millets and sorghum form subsidiary crops; the chief pulses are green and black gram, cow-pea, and the ground-nut; and the chief root-crops sweet potato, yams, and manihot (tapioca).

A SYSTEMATIC enumeration of the palms of the Philippines is given by Dr. O. Beccari in the *Philippine Journal of Science* (vol. xiv., No. 3). One hundred and twenty species are at present known to be indigenous, which, with the exception of about a dozen species of relatively wide geographic distribution, are endemic forms. In discussing the relationships of the palm-flora, Dr. Beccari concludes that the Philippine species have in great measure originated in the archipelago, but their phylogeny may be traced to species growing chiefly in Borneo, Celebes, the Moluccas, and Indo-China, excluding about a dozen species which, possessing adaptations for easy dissemination, have a rather wide distribution. A small Polynesian element is represented by Adonidia, the only genus peculiar to the archipelago, and Heterospathe. In the Philippines a few large genera have given rise to numerous species, whereas in Polynesia monotypic or oligotypic genera are numerous, and no genus contains a great number of species.

THE *Meteorological Magazine* for March gives a short notice of the work of the International Meteorological Conference held in Paris in October last, taken from the account of the conference published in Paris by the Bureau Central Météorologique. Further details will be welcomed when they are published by the meteorological authorities in our own country. The preceding meeting of the body was held at Innsbruck in 1905, so that much advance in the

science had to be reported and new methods of working arranged for, especially with regard to aviation. The magazine contains a reproduction of a photograph of the members of the conference.

THE Meteorological Office chart of the North Atlantic Ocean for February contains some notes on the origin and distribution of ice in these waters, and some account of the ice patrol of the United States Government which was resumed in 1919 after several years' interruption during the war. Two coastguard cutters have been detailed for the purpose of locating icebergs and pack-ice in the vicinity of trans-Atlantic steamship routes. During the months of April, May, and June the two vessels alternate on patrol, each taking fifteen days in the ice region, exclusive of the time taken in going to and from Boston for coal and supplies. Movements of ice are reported by wireless at fixed hours daily. At 6 p.m. (75th meridian time) ice information is sent broadcast with a 600-metre wavelength. The message is repeated three times. At 6.15 p.m. the same information is sent out, using a 300-metre wave-length. At 4 a.m. a message defining the native and southern limits of the ice is sent to the New York Hydrographic Office. Ice information is also sent at any hour to any ship with which the patrol vessel can communicate. It will be recalled that this is the work which was initiated by the *Scotia* subsequent to the loss of the *Titanic*. The chart also bears an interesting map showing the drifts on the east coast of Greenland, in Baffin Bay, and in Davis Strait of various ships that have been imprisoned in the ice, and of castaway crews during the last hundred years. The March chart gives an account of the relation of the North Atlantic ice to currents and fogs.

CHERRAPUNJI, in the Khasi Hills in India, is often cited as having the greatest known annual rainfall. According to the Indian Meteorological Department, the mean annual rainfall there is 426 in. The greatest precipitation is said to have occurred in 1861, when a rainfall of 905 in. was recorded, though doubt has been expressed as to the accuracy of this record. It appears, however, that the Cherrapunji rainfall is surpassed by records on the mountains in the Hawaiian islands. Thus Mount Waialeale is the peak (5080 ft.) of the Island of Kauai, but is inaccessible except to the most expert mountaineers. On this account it was very difficult to maintain the station, and the record has finally had to be discontinued. According to the *Monthly Weather Review* (U.S. Dept. of Agric.), vol. xlvii., No. 5, during the periods August 2, 1911–March 26, 1914 and May 31, 1915–August 13, 1917, a total of 1782 days, there was recorded on Mount Waialeale a total precipitation of 2325 in., or an average of 1·3047 in. per day. In a 365-day year this would amount to an annual precipitation of about 476 in. No records were obtained during the years 1914 and 1918, but these years were considered the wettest since the local Weather Bureau Office was established in the Hawaiian islands. Comparative estimates from trustworthy records obtained at nearby stations indicated that the rainfall at Waialeale must have exceeded 600 in. From May 21, 1915–May 30, 1916, the recorded rainfall of Mount Waialeale was 561 in. The Hawaiian islands are known for other very damp spots. Thus Puu Kukui, 5000 ft., on the Island of Maui, had a seven-year average of 369 in. (maximum 562 in. in 1918). On the Island of Hawaii, at a certain spot of 4000-ft. elevation, the rainfall in 1914 amounted to 504 in. At at least a dozen other spots, all more than 1000-ft. elevation, the rainfall in each of the years 1914 and 1918 exceeded 350 in.

TECHNOLOGIC Paper No. 123, by Mr. D. W. Kessler, of the Bureau of Standards, Washington, is devoted to the tests of the physical and chemical properties of fifty of the commercial marbles of the United States. Marble has been selected as the first stone to be tested, but the whole of the deposits of stone in the country are to come under test in course of time in order to provide the knowledge required by architects in designing structures. The tests are of tensile and compression strengths, specific gravity, porosity, absorption of water, effect of freezing, chemical composition, electrical resistivity, expansion with heat, and liability to warping. The trade name and origin of each sample are given, and the tabulated results of the tests fill twenty pages. The properties of the samples differ widely, although the specific gravities do not differ more than about 5 per cent. from each other. On heating, each sample expands, and on afterwards cooling fails to regain its original dimensions. In consequence of this, marble subjected to frequent heating and cooling is liable to warp.

SCIENTIFIC Paper 352 of the Bureau of Standards, Washington, gives the results of the measurements of the expansion of forty samples of porcelain, about the same number of samples of bakelite and similar materials, and about a dozen samples of marble and limestone, made by Messrs. W. H. Souder and P. Hidnert, of the Bureau. The samples were in the form of rods 30 cm. long and 1 cm. square section, and were heated a horizontal electric furnace. The expansions were measured by a pair of microscopes mounted on a bar of invar. For the porcelain samples the coefficients per degree Centigrade between 0° C. and 200° C. vary from 2 to 20 millionths, according to the composition, and between 200° C. and 400° C. from 3 to 11 millionths. Beryl porcelains have the smallest coefficients. For bakelite and similar materials no values can be given, as there is so much contraction on again bringing the material to its original temperature. The marbles up to 100° C. have coefficients between 5 and 15×10^{-4}, and at higher temperatures larger values. On cooling to their original temperature they show a permanent expansion. When cooled to −80° C. marble expands to nearly the same extent as when heated to 80° C., so that it has its maximum density in the neighbourhood of 0° C.

THE Science Reports of the University of Sendai, Japan, for December, 1919, contain a paper by Mr. S. Konno on the heat conductivities of metals below and above their melting points. The metals were tested in

the form of circular discs about 2 cm. thick and 2·5 cm. in diameter enclosed in a porcelain tube between iron cylinders of the same diameter. In the upper iron cylinder heat was generated by a measured electric current. The fall of temperature through the disc was determined by means of thermo-couples. For tin, lead, zinc, and aluminium the heat conductivity decreases gradually up to the melting point. At the melting point the conductivity decreases abruptly, but in the liquid state its rate of decrease with increase of temperature is slight. Bismuth increases in conductivity on melting, but change of temperature has little effect on the conductivity in either the liquid or the solid state. Antimony has its maximum conductivity at the melting point. In all cases the electrical and heat conductivities change in the same direction on melting, but neither above nor below the melting point does their quotient agree with electronic theories.

THE trouble of working gelatine plates under tropical conditions seems at last to have been overcome. In the Journal of the Royal Photographic Society for March, Mr. A. P. Agnew, of Messrs. Ilford, Ltd., describes the "Ilford tropical hardener" that is now supplied by Messrs. Johnson and Sons. Mr. Agnew found that a "quite weak solution of formalin" became very effective when certain salts were dissolved in the solution. Many sodium salts were found useful, while potassium and magnesium salts are not so effective, and ammonium salts are unsuitable. Some salts have no effect, while chlorides, bromides, and nitrates in general have an opposite action—that is, they soften the gelatine. The exposed plate is put into the suitably diluted hardening solution for three minutes, then rinsed and developed, etc., as usual. Plates so treated at temperatures varying from 100° to more than 140° F., then fixed in a plain hypo solution at 40° F., and finally washed for two hours at more than 100° F. remained firm and did not even show signs of reticulation. Such trying conditions as these would never occur in practical work.

A PHOTOGRAPHIC developing agent must be able to reduce silver bromide that has been changed into the developable condition, as by exposure to light, while under the same conditions it is unable to reduce silver bromide that has not been so changed. There are many reducing agents that make no distinction between these two states of silver bromide. Some twenty years ago Messrs. A. and L. Lumière found certain details of chemical constitution that appear to confer developing power, and since then they and others have extended the investigation. In the *British Journal of Photography* for March 26 there appears a translation of a paper by Dr. Seyewetz (of Lumière's) in which the author summarises our present knowledge of this matter. Knowing the necessary constitution, a very large number of developers have been introduced and actually put upon the market, but the greater number have commercially disappeared, because in some way or other they were inconvenient to use. Dr. Seyewetz says that it is improbable that new developers will displace those now in common use. As in the case of dyes, it seems difficult to make sensational discoveries, and there is so far no indication of the direction in which to seek for new developers that would prove acceptable, as, for example, by permitting a reduction in the period of exposure.

BESIDES the paper on H.M.S. *Hood*, read at the recent meeting of the Institution of Naval Architects by Sir Eustace d'Eyncourt, there are important articles in the *Engineer* and *Engineering* for March 26 dealing with this ship. The building was commenced in April, 1916, at the Clydebank yard of Messrs. John Brown and Co., Ltd., the first of the main belt armour-plates (32 tons each) reached the yard in June, 1918, the ship was launched on August 22, 1918, and the fitting out was completed in January of this year, when the huge ship passed down the Clyde to the open sea. On the trial trips the turbines developed 157,000 shaft-horse-power, the speed attained being 32 knots. The overall length is 860 ft., the extreme breadth 104 ft., the mean load draught 28·5 ft., and the displacement at load draught 41,200 tons. The hull is fitted with a bulge or blister for securing the ship against effective attack by torpedo. The armour ranges from 12 in. thick amidships to 5 in. aft. The deck over the magazines is 3 in. thick. There are eight 15-in. guns, all on the middle line, each pair being mounted in an armoured barbette. The secondary armament consists of twelve 5·5-in. guns, and there are four 4-in. anti-aircraft guns mounted on the superstructure. The ship is fitted with six torpedo tubes for 21-in. torpedoes. There are eight electric generators, four of which are driven by reciprocating engines, two by geared high-speed impulse turbines, and two by eight-cylinder Diesel oil engines. About 360 electromotors are installed, ranging from ¼ to 140 brake-horse-power.

SIR ALFRED EWING is bringing out almost immediately, through the Cambridge University Press, a treatise on "Thermodynamics for Engineers," in which the author aims at making readers familiar with the physical bearing of the fundamental ideas of the subject by means of an elementary introduction and by dealing with practical problems in the theory of heat-engines and of refrigeration. A more mathematical treatment of general thermodynamic relations follows. There will also be an appendix sketching in outline the molecular theory of gases, with special reference to internal energy and specific heat. Another book on the list of the Cambridge University Press is by Prof. A. S. Eddington, entitled "Space, Time, and Gravitation." It is promised for the coming summer.

A FORTHCOMING addition to Sir Edward Thorpe's series of Monographs on Industrial Chemistry is of current interest, seeing that it will treat of "The Manufacture of Sugar from the Cane and Beet." It will be by T. H. P. Heriot, of the Royal Technical College, Glasgow, and give special attention to the principles underlying factory operations.

ERRATUM.—On p. 138 of NATURE of April 1, col. 1, line 15 from the bottom of the page, bx should be $bx^{\frac{2}{3}}$ in the equation $y=ax^{\frac{1}{3}}+bx^{\frac{2}{3}}$. The fractional index was broken during paging of the issue.

Our Astronomical Column.

CAPELLA.—A knowledge of the parallax of Capella is of special interest owing to the close resemblance of this star's spectrum to that of the sun and the fact that it is a spectroscopic binary with a period of 104¼ days. Prof. F. Schlesinger and Mr. Z. Daniel have made a new determination at the Allegheny Observatory (*Astr. Journ.*, No. 765). They observed both the principal star and Furuhjelm's distant companion. The weighted mean parallax (absolute) is $0·068'' \pm 0·006''$. Earlier results are: Elkin, $0·079''$; Jost, $0·051''$; and Adams and Joy, $0·105''$.

The star B.D.$+61°$ 2068, the proper motion of which is $0·77''$, was also measured for parallax at Allegheny, the large value $0·139'' \pm 0·007''$ (absolute) being found. The corresponding absolute magnitude is 9·3 visual and 10·5 photographic.

Attempts were made some twenty years ago to detect the duplicity of Capella telescopically. It was considered for a time that the 28-in. equatorial at Greenwich gave an elongated image, but, in view of the failure of the great American refractors, little reliance was placed on this. A letter from Prof. Hale dated January 6 last (*Observatory*, March) announces that success has been obtained by interferometer methods with the 100-in. reflector. It was deduced that the separation on December 30, 1919, was $0·042''$, and the position angle 148° or 328°. It is hoped that a continued series of such observations will give a determination of the inclination of the orbit, and hence of the masses of the components. There is even a prospect that the diameters of such giant stars as Sirius, Antares, and Betelgeux may be determinable with the interferometer.

CAPE OBSERVATIONS OF THE SUN, MERCURY, AND VENUS.—The Cape observations of these bodies, made with the new transit circle and the travelling-wire micrometer during the five years 1907–11, have just been distributed, together with a discussion of results. The corrections to the equinox derived from the three bodies are in good accord, and indicate that Newcomb's system of right ascensions needs the constant correction $-0·05$s. The corrections to Newcomb's longitudes of perihelia of Mercury, Venus, and the earth are $-0·78''$, $+6·8''$, and $-7·4''$ respectively. These are of interest in relation to the Einstein controversy. Newcomb applied the corrections to the centennial motion of the perihelia given by the Asaph Hall hypothesis, according to which gravitation varies as $r^{-2·0000001612}$. This formula gives $+43·37''$, $+16·98''$, and $+10·45''$ for Mercury, Venus, and the earth, whereas Einstein's formula gives $+42·9''$, $+8·6''$, and $+3·8''$. It will be seen that the adoption of Einstein's law of gravitation by the Nautical Almanac would mean a movement towards Newton's law, not a departure from it.

The following semi-diameters of Mercury and Venus at distance unity were deduced from the observations:—Mercury (latitude observations) $3·36'' \pm 0·03''$, (longitude) $3·79'' \pm 0·17''$; Venus (latitude) $8·67'' \pm 0·03''$, (longitude) $8·07'' \pm 0·04''$. The tabular values are $3·34''$ and $8·40''$. As these depend to a considerable extent on observations made during transits, they are likely to be somewhat too small.

The Cape results may be too large owing to irradiation, but, since all the observations were made in daylight, this is not likely to be excessive. But as the mass of Venus is only five-sixths that of the earth, it is probable that its diameter is also smaller, whereas the Cape figures make it equal to the earth.

Basic Slag and its Uses in Agriculture.

AN important discussion on basic slag and its uses in agriculture, organised by the Faraday Society, at which a number of leading representatives of the steel makers and of agriculturists were present, was held in the rooms of the Chemical Society on March 23. Prof. F. G. Donnan presided over the meeting.

The discussion was opened by Dr. E. J. Russell, who gave a general survey of the subject and indicated the nature of the problems concerned. The basic slag produced by the basic Bessemer process had earned a high reputation as a potent agent in the improvement of poor pastures. The effect is indirect, and results from a stimulation of the white clover—whether the action of the phosphate is on the clover plant or on the nodule organism is not yet certain. But whatever the reason, the effect on pasture land is very marked, and British agriculturists could absorb some 300,000 or 400,000 tons a year if this could be produced. Unfortunately for agriculturists, however, the Bessemer process is in danger of supersession, and the basic open-hearth process is taking its place. This new process gives two kinds of slag, both poorer than the Bessemer slag in phosphates.

One of these slags is made by the use of calcium fluoride, and in consequence is less soluble than the other. The great problem before the investigator at the present time is to enrich the low-grade slags so as to make them better worth grinding and transport than they now are.

Open-hearth slag made without fluorspar has hitherto proved practically as effective as the old Bessemer slag when compared on the basis of equal amounts of phosphorus. Fluorspar slag has proved to be of less value, although considerably better than was at first thought.

It is usually assumed, though by no means proved, that the phosphate is the only effective constituent in the slag. At various times it has been suggested that lime, manganese, or iron might be useful; it is also possible that slag contains a silico-phosphate which might have more value than the ordinary phosphate.

The enrichment of the slag cannot apparently be brought about by any change in the pig iron, owing to the great disparity in price between steel and slag; fractionation is, however, possible, or the addition of ground mineral phosphate to the molten slag. Further experiments would be necessary before any decision can be made.

Sir Thomas Middleton gave an account of the place of basic slag in the agricultural system of this country. British farmers tend more and more to produce animal rather than human food. The two main human food-crops—wheat and potatoes—occupied no more than 3,000,000 acres before the war, while 36,000,000 acres were devoted to the crop requirements of cattle and sheep. The value of the wheat and potatoes was about 27,000,000*l.*, while the live stock brought in some 125,000,000*l.* The supreme importance of basic slag arises from the fact that it helps to produce animal food; it is essentially a pasture fertiliser. In the Cockle Park experiments the untreated pasture yielded about 20 lb. of lean meat per acre per annum; after treatment with basic slag the yield rose to 105 lb. of meat per acre. The results of many other experiments show that on thousands of acres in this country the yield of meat might be increased by the use of basic slag. Nor are the advantages of slag confined to grass land. By ploughing up more grass, valuable additions could be made to the tillage land, and if the remaining grass were treated with basic slag there

would be no falling off in total yield, in spite of the diminished area.

Mr. Bainbridge gave an account of the experiments by Dr. Stead and Mr. Jackson on the solubility of basic slag in citric and carbonic acids. The reason why fluorspar makes the phosphoric acid in slag insoluble is that a reaction occurs between fluoride and phosphate, producing an artificial apatite, which, as regards insolubility, resembles natural fluorapatite. Even the most soluble phosphatic slags undergo this change and become insoluble on melting with fluorspar. Carbonic acid, after long-continued attack, generally dissolves out more phosphoric acid than a single attack by the standard citric acid.

Mr. G. Scott Robertson gave details of the field tests made to compare the effect of various types of open-hearth basic slags on grassland. These experiments were made in Essex on London clay, Boulder clay, and chalk. They show that all the phosphatic slags are effective fertilisers; but there are important differences in the agricultural effects, which are not connected with solubility according to the citric acid test; indeed, this test affords no indication of the fertilising value of open-hearth slags. Details of the botanical examination of the plots showed the striking effect of the basic slags in reducing the amount of bare space and in increasing the amount of clover.

Mr. Daniel Sillars made an important contribution from the metallurgical side, discussing the formation of basic slag in the manufacture of steel. The phosphide of iron, Fe_2P, in which state of combination phosphorus exists in molten iron, is oxidised by reactions of the type—

$$5Fe_3O_4 + 2P = 15FeO + P_2O_5$$
$$5Fe_3O_4 + 8P = 15Fe + 4P_2O_5.$$

The P_2O_5 formed may combine with FeO to form $Fe_3(PO_4)_2$, which, however, is unstable in the presence of a large excess of iron, and a reaction such as $Fe_3(PO_4)_2 + 11Fe = 8FeO + 2Fe_2P$ results, and it is in consequence of this reaction that the acid process of steel-making is unable to remove phosphorus. In the basic process the presence of lime affords an opportunity to the phosphoric acid to form a stable body by the reaction—

$$Fe_3(PO_4)_2 + 4CaO = Ca_4P_2O_9 + 3FeO.$$

The calcium phosphate formed is only feebly attacked and decomposed by the metallic iron, but manganese and carbon attack it more vigorously and cause the phosphoric acid to be reduced and the metal to be re-phosphorised. These reactions are, of course, proceeding concurrently, and it is necessary to maintain a certain concentration of ferrous oxide in the slag to minimise, so far as possible, the tendency to re-phosphorisation. Re-phosphorisation is probably due to the reaction between ferrous phosphate and lime being slightly reversible, whereby a small concentration of ferrous phosphate is always present, which is reduced by the carbon unless a source of oxygen is supplied by ferrous oxide in the slag.

In ordinary practice the open-hearth process is carried out by allowing the slag formed by the oxidation of the silicon, phosphorus, and manganese to flow over shutes made in the fore-plates into slag-pots under the furnaces, and no attempt is usually made to remove more slag than that which flows out naturally when the level of the slag in the furnace is higher than the level of the fore-plate. The slag left behind is carried on, and forms part of the finishing slag, which latter is therefore much greater in volume, and therefore lower in phosphoric acid, than the slag removed in the middle of the process. By this method of operation the time spent in tapping the furnace for separation of the slag and for the formation of a new slag is saved, but the slag is inferior both in richness and in citrate solubility if that still forms a criterion of excellence to the agriculturist.

Mr. Ridsdale took part in the discussion, and exhibited specimens of slags examined in the classic investigations by Stead and Ridsdale; and Mr. W. S. Jones contributed a paper on the improvement of low-grade basic slags.

As a result of the discussion it was decided to ask the Ministry of Agriculture to form a Committee which should study possible practical steps to effect improvement in quality and in quantity of the phosphatic slags.

Verification of Screw Gauges for Munitions of War.

THE *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* (November–December, 1919, No. 6) contains an article by M. Cellerier, of the Conservatoire des Arts et Métiers, on the verification of screw gauges, with particular reference to the methods advocated by Mr. Bingham Powell, who was engaged in the United States during the war as Inspector of Gauges and Standards for the British Ministry of Munitions. These methods related chiefly to the measurement of the full, effective, and core diameters; the verification of pitch was neglected until quite a late period of the war, owing to the lack of instruments possessing the requisite precision and rapidity.

Extreme accuracy is of the highest importance in measurements of pitch, as any error in the pitch makes it necessary for the maximum limit of effective diameter to be reduced by double the amount of this error if the gauge is to be accepted as correct. Where the permissible deviations are very small, an error in pitch of a few ten-thousandths of an inch may thus completely annihilate the tolerance on effective diameter. Inaccuracies of pitch are often regarded as essentially progressive; but this is not always the case, as deformations due to hardening may introduce variable errors of quite appreciable magnitude. The method frequently adopted of verifying the pitch by measurements made on a length comprising a number of threads is accordingly much less trustworthy than the practice, long in vogue in France, of testing separately a number of consecutive threads.

For the latter process measuring machines of the pattern used at the National Physical Laboratory are particularly suitable, but at the time when the demand for extreme accuracy in screw gauges for war-work first became pressing it was impossible to obtain one of these machines in America without considerable delay, and accordingly Mr. Powell found it necessary to devise an instrument on the spot. He dispensed with the optical contrivance which forms an essential feature of the laboratory machine, and substituted for the spherical contacts a lever terminating in a small sphere which rests freely in the screw and can be guided conveniently in the axial plane from one thread to another. The lever consists of a very light needle, arranged in such a way that the apparatus can also be used for testing internal screws or nuts by means of appropriate casts taken by an ingenious and delicate method, but only a small segment of the internal thread can be obtained in this way for testing purposes.

As regards the measurement of diameters, although an ordinary micrometer will suffice for the external dimension, it is not suitable for determining either the effective or the core diameter. Before testing the effective diameters it is necessary to know the errors o' the pitch, in order that the appropriate reductions may be made in the maximum limit of tolerance. A micrometer with point contacts should never be used alone for the effective diameter, as it bears only on projecting parts, and, further, the points wear down quickly. Even when new, its contacts for screw-threads rarely have the correct angle. It is, however, a useful check on results obtained by the aid of wire contacts, especially for investigating anomalies which may be apparent in these results.

Mr. Powell has made a special study of wire contacts for testing effective diameters. He employs systematically two series of wires for each pitch of screw. One series is such that the wire bears exactly on the theoretical effective diameter of a perfect screw; in the other series the wire bears on the sides of the screw not far from the outer edge, but so as to avoid the rounded-off part in Whitworth threads. The correct diameters for the series are calculated from a simple formula. The wires, which are finished by grinding, must be perfectly cylindrical, and their diameters have to be ascertained to an accuracy of 0·00001 in.; any error in the diameter of the wire is multiplied threefold in the result obtained for the effective diameter. They are made of hardened steel, and are about 2 in. in length, or longer for very large screws; but their exact adjustment is only necessary over about half an inch in the centre of the length.

The verification of internal screws may be effected simply by employing either an external screw having the correct dimensions for external, effective, and core diameters, or a screw correct for maximum and effective diameters, but slightly small for core diameter. A plug is also used in this case for verifying the minimum diameter of the internal screw. If these gauges enter the nut, the test is regarded as satisfactory; but, in reality, this is not always the case, as the external screw may appear to give a good result even if it bears on only one diameter of the nut; while the other diameters may be far outside the limit of tolerance. A large number of different gauges are necessary in order to verify separately every diameter of an internal screw.

Mr. Powell has drawn up a list of equipment required in the verification of screw gauges. This includes a pitch-measuring machine, an apparatus for obtaining casts of internal screws, a projecting arrangement, an instrument for measuring the three characteristic diameters of external screws, a collection of suitable wire contacts, small triangular prisms for verifying core diameters, standardised micrometers, Johansson gauges, and a complete set of standards for measuring diameters, pitch, and form of internal threads.

A theoretical explanation of the principles of the methods employed would have been of interest. In its absence some doubts arise, for example, as to the practical value of profiles of screw-threads projected on screens. Again, the contacts of small cylindrical wires on the helicoidal surfaces of threads cannot be regarded as the same as that of a circle and two intersecting straight lines, although the formulæ employed, which are stated without proof, appear to be founded on a consideration of this kind. In conclusion, Mr. Powell's methods are by no means entirely novel, but they were very successful during the war, and will no doubt be found instructive by all those engaged in the manufacture and verification of screw gauges.

The Composition of Salvarsan.

WHEN salvarsan was first introduced for use in medicine the German manufacturers stated that it contained "about 34 per cent. of arsenic," which is the percentage calculated for a pure dihydroxydiamino-arsenobenzene dihydrochloride, $C_{12}H_{12}O_2N_2As_2,2HCl$. This statement was afterwards altered to "the arsenic content of the preparation corresponds to the formula $C_{12}H_{12}O_2N_2As_2,2HCl,2H_2O$ as a result of Gaebel's observation that the drug loses 7·6 per cent. by weight on drying, and contains only 31·5 per cent. of arsenic." Last year Kober, in the United States, ventured the opinion that the combined solvent in salvarsan is not water, but methyl alcohol, and suggested that the latter might be the cause of variable toxicity in salvarsan—a suggestion which is rather far-fetched in view of the fact that, even on Kober's assumption, a maximum normal dose of salvarsan could contain only 0·04 gram of methyl alcohol.

This and other questions connected with the composition of salvarsan have been investigated in the Wellcome Chemical Research Laboratories, and in a paper contributed to the meeting of the Chemical Society on March 18 Messrs. Fargher and Pyman showed that the combined solvent in salvarsan is water; and though small quantities of methyl alcohol may also be present, due to the use of this alcohol in the liquid from which the drug is precipitated, the amount never exceeds 1·4 per cent., and is frequently *nil*. It was also found that the sulphur always present in commercial salvarsan as a result of the use of sodium hyposulphite as a reducing agent in its preparation, occurs in at least two forms: (1) as a sulphaminic acid, probably "salvarsan" monosulphaminic acid hydrochloride, and (2) attached directly to arsenic; whilst a third portion may be in physical association with salvarsan, which has certain colloidal properties.

These results support the conclusion expressed in the recent Special Report (No. 44) of the Medical Research Committee, that though salvarsan is not a chemically pure substance, there is no known chemical impurity with the presence or proportion of which its varying toxicity can be brought into relation. In this connection it is interesting to note that a specially pure salvarsan free from sulphur, prepared by Messrs. Fargher and Pyman, was tested by the Medical Research Committee and shown to be more than normally toxic. Chemical testing alone is, therefore, insufficient to determine whether any particular batch of salvarsan is suitable for medical use, and it is on this account that the Medical Research Committee has elaborated the system of biological testing, described in the Special Report already referred to, to control the issue of salvarsan in this country. It is satisfactory that the Committee is able to report that, from the point of view of permanence of effect, the British and French salvarsan preparations are therapeutically as good as the German.

University and Educational Intelligence.

THE governors of the Huddersfield Technical College have received a gift of 2000*l*. from Mrs. Mary Blamires, widow of Alderman Joseph Blamires, in memory of her late husband, himself a former student, and afterwards a governor, of the college. The scholarship is to be used for the promotion of research in chemistry.

THE headquarters of the Yorkshire Summer School of Geography, now being organised by the University of Leeds, will this year be the County School, Whitby,

the school buildings having been kindly lent by the governors for this purpose. The object of the Summer School is to provide theoretical and practical instruction in the methods of geography and to furnish opportunities for the discussion and elucidation of problems connected with the teaching of the subject. The course will consist of lectures, laboratory work, field work, and demonstrations. Lectures will begin on Morning morning, August 2, and the course will end on Saturday, August 21. Among the lecturers will be Prof. Kendall (professor of geology in the University of Leeds), Dr. A. Gilligan (lecturer in economic geology), Mr. C. B. Fawcett (lecturer in geography), Dr. W. G. Smith (lecturer in agricultural botany at the Edinburgh and East of Scotland Institute), and Mr. W. P. Welpton (lecturer in education and master of method in the University of Leeds). Applications for tickets should be made to the Secretary of the Yorkshire Summer School of Geography, The University, Leeds.

BEDFORD College for Women, a constituent college of the University of London, and the largest and oldest university college for women in England, has issued an appeal for funds. At the moment, when there is an overwhelming demand by women for higher education and training, the college must either refuse admission to highly suitable students and starve or close down certain departments, or it must enlarge its buildings and increase its endowments. Seven hundred students now crowd into buildings adapted for four hundred and fifty, with the result that in many cases classes have to be triplicated and class-rooms and apparatus shared between different departments. A sum of 100,000*l*. is needed for additional lecture-rooms and laboratories. A second 100,000*l*. is required for endowment, notably for scholarships, the various departments of science, the department of social studies, and the training department. A third 100,000*l*. is badly needed for a hostel. An opportunity for acquiring an admirable site just outside Regent's Park has presented itself. Whether the college can take advantage of this must depend on the generosity of the public. It should, perhaps, be emphasised that, apart from such developments, the income of the college is by no means sufficient for its present needs in view of the enormously increased cost of maintenance and the necessity for raising all salaries. The work of universities in the past could never have been done had there not lived generous men and women who believed they could render no greater public service than by endowing colleges and thus furnishing opportunities for rich and poor to acquire sound learning. May we hope that a like generosity and a like belief exists to-day? The Queen's interest in the college is well known, and has taken the practical form of giving a donation. Subscriptions should be sent to Viscountess Elveden, hon. treasurer of the Bedford College Endowment and Extension Fund, Bedford College, Regent's Park, N.W.1.

Societies and Academies.

LONDON.

Royal Society, March 18.—Sir J. J. Thomson, president, in the chair.—W. B. **Brierley**: A form of *Botrytis cinerea* with colourless sclerotia. A form of *Botrytis cinerea* with colourless sclerotia is described. This was obtained by the isolation and growth of a colourless sclerotium, which was formed in a culture of a normal strain derived from a single spore. The primary origin of the change resulting in the albino form is located in the hyphal mother-cell from which the initial colourless sclerotium arose. Lotsy's dictum that "certainty of purity is a *conditio sine qua non* to obtain proof of the existence of mutation in living beings" is accepted, and it is shown that such a state is possibly not realisable in the fungi. It is suggested that somatic fusions resulting in a change of genotypic values are the mechanism whereby evolution in the fungi has taken place.—R. R. **Gates**: A preliminary account of the meiotic phenomena in the pollen mother-cells and tapetum of lettuce (*Lactuca sativa*). In a preliminary study of meiosis in the pollen development of lettuce, several points have appeared which have a general bearing on cytological conceptions and the problems of genetics. The exceptional condition has been found in lettuce, in which every intergrade occurs between pollen mother-cells and tapetal cells. Even synapsis has been observed in binucleate tapetal cells, which emphasises the physiological aspects of the synaptic contraction. The tapetal cells are peculiar in being often very much elongated and lying lengthwise of the anther. Ultimately they break down and form a plasmodium surrounding the pollen-grains. Cytomyxis also occurs, though rarely, during the stage of synapsis in the pollen mother-cells.

March 25.—Sir J. J. Thomson, president, in the chair.—A. R. **Forsyth**: Note on the central differential equation in the relativity theory of gravitation. The critical equation in Prof. Einstein's theory is—

$$\left(\frac{du}{d\phi}\right)^2 + u^2 = \frac{c^2-1}{\lambda^2} + 2\frac{m}{\lambda^2}u + 2mu^3,$$

so that
$$\left(\frac{du}{d\phi}\right)^2 = 2m\,(u-\alpha)\,(u-\beta)\,(u-\gamma),$$

where α, β, γ are proved to be real and positive for the known planetary bodies in the solar system, and are arranged so that $\alpha>\beta>\gamma$.

There is no need for initial approximation. The equation can be integrated exactly, in terms of elliptic functions. The integral is—

$$u=\gamma+(\beta-\gamma)\,\frac{1+cn\,\{(\phi-\varpi)/\rho\}}{1+dn\,\{(\phi-\varpi)/\rho\}}$$

where $\phi=\varpi$ at perihelion; the modulus of the elliptic functions is given by—

$$k^2=\frac{\beta-\gamma}{\alpha-\gamma} \text{ and } \rho=\{2m\,(\alpha-\gamma)\}^{-\frac{1}{2}}.$$

Further, the advance of the perihelion in one revolution is-

$$4\rho K-2\pi,$$

where K is the complete first elliptic integral with the modulus k. These expressions are accurate (and not approximate) in relation to the initial equation. For approximations in connection with the known members of the solar system, k^2 is small, so that K is slightly greater than $\frac{1}{2}\pi$, and ρ is slightly greater than unity. The advance of the perihelion is $2\pi.3m^2/\lambda^2$; and the value of u is—

$$\frac{m}{\lambda^2}\{1+e\cos(\phi-\varpi)+\frac{m^2}{\lambda^2}e^2\sin^2(\phi-\varpi)$$
$$+3\frac{m^2}{\lambda^2}e\,(\phi-\varpi)\sin(\phi-\varpi)\}.$$

—R. D. **Oldham**: The frequency of earthquakes in Italy in the years 1896 to 1914. The paper is an attempt to discover whether there is any variation in the frequency of earthquakes which can be attributed to the stresses set up by the gravitational attraction of the sun and the moon. In addition to some small and more or less doubtful variations, there was found to be a very marked maximum frequency about the time of the new moon, when the declinations of the sun and moon were of the same sign and at the full

when they were opposite, together with an equally marked minimum frequency at the full when the declinations were the same, and at the new when they were opposite. At the quarters the frequency is about average; at the times of minimum the frequency is about one-third, and at the maximum about five-thirds, of the average. The magnitude, no less than the fact that it is continuously recognisable throughout the record, shows that the variation is a real one, and it is difficult to find any other cause than the effect of the stresses set up by the gravitational attraction of the sun and the moon.—A. F. **Dufton**: A new apparatus for drawing conic curves. With the apparatus described in this paper the conic is drawn as the polar reciprocal of a circle. A four-bar linkage constrains a pen to trace the locus of the pole of a fixed straight line enveloping a circle upon paper pinned to a rotating drawing-board. The instrument draws conics with precision. It traces the curves at one sweep, and is applicable to all conics.—Capt. J. W. **Bispham**: An experimental determination of the distribution of the partial correlation coefficient in samples of 30. The distributions are described of the observed values of the partial and total correlations from 1000 samples of 30 each. The three attributes of the sampled (artificial) population are uncorrelated, so that observed values of the correlations are departures from the true value, which is zero in each case. The three groups of 1000 total correlations observed are shown to be nearly Gaussian in form, and to be in very close accord with the distributions predicted in general form by R. A. Fisher, and evaluated in detail in an important co-operative study described in *Biometrika*. The distribution of partial correlations is compared with the Gaussian, the Pearson Type II., and the theoretical distribution of *total* correlations referred to above. It is found to be closely fitted by the latter, and not to show significantly higher dispersion than is indicated by the usual expression for the standard deviation of total correlations, viz. $1-\rho^2/\sqrt{n-1}$. Some important practical bearings of the result are indicated.

PARIS.

Academy of Sciences, March 1.—M. Henri Deslandres in the chair.—G. **Humbert**: The number of classes of positive quadratic forms of Hermite, of given discriminant, in an imaginary quadratic body.—Em. **Bourquelot** and M. **Bridel**: A new glucoside capable of hydrolysis by emulsin, scabiosine. This glucoside was extracted from the root of *Scabiosa succisa* (devil's bit scabious). Details of its isolation and hydrolysis by dilute sulphuric acid and by emulsin are given.—A. **Rateau**: The flight altitude which corresponds to a minimum consumption of petrol per kilometre, and the calculation of the best propeller for a given aeroplane.—A. **Righi**: The experimental bases of the theory of relativity.—A. Mesnager was elected a member of the section of mechanics in succession to the late Marcel Deprez, and A. Fowler a correspondant for the section of astronomy in succession to the late Edmund Weiss.—N. E. **Nörlund**: The convergence of certain series.—A. **Rosenblatt**: A theorem of A. Liapounoff.—M. T. **Huber**: A rational theory of pugging in reinforced concrete, considered as thin plates.—Ch. **Fremont**: The resistance of steels to cutting by tools. It is well known that steels possessing the same resistance to fracture by tension may differ greatly in the ease with which they can be cut by tools. Instead of the usual calculation, maximum load divided by initial cross-section, the author proposes the term "final resistance," obtained by dividing the maximum load by the actual cross-section of the broken test piece.—J. **Guyot** and L. J. **Simon**: The combustion of methyl esters with a mixture of sulphuric and chromic acids. Analytical figures are given for the wet combustion of sixteen methyl compounds of different types, and the carbon dioxide produced is shown to be practically theoretical.—A. **Mailhe** and F. **de Godon**: The preparation of fatty acids by the catalytic oxidation of the primary alcohols. With reduced copper as catalyst, and at temperatures between 260° C. and 270° C., the primary alcohols with air give substantial yields of the corresponding acids. Aldehydes are always produced at the same time, and in some cases more aldehyde than acid is produced.—C. **Schlumberger**: Attempts at the electrical prospecting of the subsoil.—Mme. Z. **Gruzewska**: Contribution to the study of laminarine from *Laminaria flexicaulis*. Laminarine cannot be considered as belonging to the dextrin group, having regard to its lævorotatory power and its resistance to the action of acids and alkalis. Its digestibility by the plant diastases shows it to be a reserve material in the marine algæ.—A. **Sartory**: A new fungus of the genus Aspergillus isolated from a case of onychomycosis.—H. **Piéron**: The variation of energy as a function of the time of stimulation for foveal vision.—A. **Vernes** and R. **Douris**: The action of certain precipitates on the solution of the red blood corpuscles.—R. **Anthony**: The exorchidia of Mesoplodon and the re-ascent of the testicles in the course of the phylogeny of the Cetaceans.—J. L. **Lichtenstein**: The parasitism of *Aphiochaeta (Phora) fasciata*.—E. F. **Galiano**: Some histological details of the arterial heart of *Sepia officinalis*.—G. **Riquoir**: Colloidal complexes and sera. A preliminary injection of a colloid, followed after an interval by an injection of a curative serum, may produce beneficial effects in cases where the serum injection alone has proved to be without effect. Several examples are detailed.—A. **Trillat**: The influence of the variation of the barometric pressure on the microbial droplets in suspension in the atmosphere.

Diary of Societies.

THURSDAY, APRIL 8.

INSTITUTION OF AUTOMOBILE ENGINEERS (Graduates' Section) (at 28 Victoria Street), at 8.—W. D. Pile: The Use of Benzol.
ROYAL SOCIETY OF MEDICINE (Obstetrics and Gynæcology Section), at 8.

FRIDAY, APRIL 9.

ROYAL ASTRONOMICAL SOCIETY, at 5.—E. E. Barnard: Naked-eye Observations of Nova Aquilæ III.—Col. E. H. Hills: The Suspended Zenith Telescope of Durham Observatory, Part I.—Rev. A. L. Cortie: The Great Sun-spot Groups and the Magnetic Storm, 1920 March 22–23.
CONCRETE INSTITUTE, at 6.—T. J. Clark: The Uses of Concrete.
MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6.
INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—C. H. Woodfield and Others: Discussion on Cranes: Their Use and Abuse.
JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—A. H. Howe: The Development and Manufacture of the Thermionic Valve.
ROYAL SOCIETY OF MEDICINE (Anæsthetics Section), at 8.15.—(Annual General Meeting), at 8.30.—Mrs. D. Berry and Others: Discussion on Anæsthesia in Operations on the Thyroid Gland.

MONDAY, APRIL 12.

VICTORIA INSTITUTE (at the Central Hall, Westminster), at 4.30.—Rev. Dr. J. E. H. Themson: The Pentateuch of the Samaritans: When They Got It, and Whence.
ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge), at 5.—Col. Sir Sidney Burrard: A Brief Review of the Evidence upon which the Theory of Isostasy is Based.
ROYAL INSTITUTION OF GREAT BRITAIN (General Meeting), at 5.
SOCIETY OF ENGINEERS (at Geological Society), at 5.30.—Prof. E. R. Matthews: (1) Flood Prevention Works at Troon, Ayrshire; (2) The Action of Sea Water on Concrete.
SURVEYORS' INSTITUTION (Junior Meeting), at 7.
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.
ARISTOTELIAN SOCIETY (at 74 Grosvenor Street), at 8.—J. W. Scott, Dr. G. E. Moore, Prof. H. Wildon Carr, and Prof. G. Dawes Hicks: Symposium on Is the "Concrete Universal" the True Type of Universality?
ROYAL SOCIETY OF ARTS, at 8.—Dr. W. Rosenhain: Aluminium and its Alloys (Cantor Lecture).
SOCIETY OF CHEMICAL INDUSTRY (at Chemical Society), at 8.—Dr. Winifred E. Brenchley and E. H. Richards: The Fertilising Value of Sewage Sludges.—Dr. E. P. Perman: A New Test for Incorporation.—Prof. T. M. Lowry and L. P. McHatton: Experiments on Decrepitation.
INSTITUTION OF ELECTRICAL ENGINEERS (Students' Meeting) (at Institution of Mechanical Engineers), at 8.—Joint Discussion with the Graduates' Association of the Institution of Mechanical Engineers on The Six-hour Working Day and its Effect on Industry.

TUESDAY, APRIL 13.

ROYAL HORTICULTURAL SOCIETY, at 3.—Dr. A. B. Rendle: Plants of Interest in the Day's Exhibition.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Major G. W. C. Kaye: Recent Advances in X-ray Work.
INSTITUTION OF CIVIL ENGINEERS, at 5.30.—Lt.-Col. J. K. Robertson: Richborough Military Transportation Depôt.—Major F. O. Stanford: The War Department Cross-Channel Train-Ferry.
ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Arthur Willey: An Apodous *Amia calva*.—H. A. Baylis and Dr. Clayton Lane: A Revision of the Nematode Family Gnathostomidæ.—Dr. W. J. Dakin: The Onychophora of Western Australia.—A. M. Altson: The Life-history and Habits of Two Parasites of the Blowfly.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Scientific and Technical Group), at 7.—A. C. Banfield: Prisms.—A. J. Munro: Machinery used in the Manufacture of Photographic Plates.
QUEKETT MICROSCOPICAL CLUB (at 20 Hanover Square), at 7.30.
ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—A. O. Neville: The Western Australian Aborigines: Their Treatment and Care.

WEDNESDAY, APRIL 14.

ROYAL UNITED SERVICE INSTITUTION, at 3.—Lt.-Col. J. Shakespear: Recent Events on the Assam Frontier.
ROYAL SOCIETY OF ARTS, at 4.30.—J. Thorp: The Fundamental Basis of Good Printing.
BRITISH PSYCHOLOGICAL SOCIETY (Education Section) (at London Day Training College), at 6.—C. A. Claremont: The Functioning of the Will: A Suggested Application of Herrington's Work on Reflexes.
ROYAL AERONAUTICAL SOCIETY (at Royal Society of Arts), at 8.—Capt. P. D. Acland: Trans continental Flying.
INSTITUTION OF AUTOMOBILE ENGINEERS (at Institution of Mechanical Engineers), at 8.—Dr. W. H. Hatfield: The Most Suitable Steels for Automobile Parts.
SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—A. E. Parkes: The Turbidity Temperature of Fats, Oils, and Fatty Acids, Part I.—Dr. G. W. Monier-Williams: The Interpretation of Milk Records.—Dr. A. F. Joseph and G. A. Freak: The Loss of Free Ammonia from Drinking-Water Samples.—E. Sinkinson: A Decanting and Filter-Washing Machine.

THURSDAY, APRIL 15.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—S. Skinner: Ebullition and Evaporation.
ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir George Buchanan: The Ports of India: Their Administration and Development.
LINNEAN SOCIETY, at 5.—Capt. F. Kingdon Ward: Natural History Exploration on the North-east Frontier of Burma.—R. Paulson: Exhibition of Lantern-slides illustrating Definite Stages in the Sporulation and Gonidia within the Thallus of the Lichen *Evernia prunastri*, Ach.
ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.
INSTITUTION OF MINING AND METALLURGY (Annual General Meeting) (at Geological Society), at 5.30.
CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Prof. W. Ripman: Spelling Reform.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Dr. C. V. Drysdale: Modern Marine Problems (Kelvin Lecture).
OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—J. Weir French: The Unaided Eye, Part III.—R. R. Walls: The Rock Crystal of Brazil.
CHEMICAL SOCIETY, at 8.

FRIDAY, APRIL 16.

CONCRETE INSTITUTE, at 6.—E. Fiander Etchells: Submission of Plans to Local Authorities.
INSTITUTION OF ELECTRICAL ENGINEERS (Students' Meeting) (at Faraday House), at 7.—J. Scott-Taggart: The Vacuum Tube as a Transmitter and Receiver of Continuous Waves.
INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—J. E. Baty and Others: Discussion on Planing *v.* Milling.
TECHNICAL INSPECTION ASSOCIATION (at Royal Society of Arts), at 7.30.—F. R. Wade: Labour Unrest—Its Causes and Cure.
ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Sir Ernest Rutherford: Development of Radiology (Mackenzie Davidson Memorial Lecture).
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. J. A. McClelland: Ions and Nuclei.

SATURDAY, APRIL 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. W. H. Eccles: The Thermionic Vacuum Tube as Detector, Amplifier, and Generator of Electrical Oscillations.

The Encourage[redacted]very.

DURING the past few years much has been done by the State to provide facilities for research, but it is not too much to say that even now neither the public nor our statesmen understand the debt they owe to the peculiar and rare geniuses to whom the greatest discoveries are due, or that any attempt has been made to discharge it. Grants for research expenses or for the maintenance of research workers are available from various sources, and much valuable work is being carried on through this aid. What is wanted to complete the scheme is a fund from which pensions or other substantial money grants could be made for scientific discoveries of an epoch-making character, somewhat in the manner of the award of the Nobel prizes. We referred a few weeks ago (March 4, p. 18) to a deputation which waited upon Mr. Balfour, Lord President of the Council, to urge that a sum of about 20,000*l.* should be set aside annually for this purpose; and we trust that this modest provision for the encouragement of genius will be forthcoming.

The January number of the Journal of the British Science Guild contains a carefully prepared report on the subject of awards of this nature, with particular reference to medical discovery. The committee which presented the report consisted of eleven men of scientific distinction—five representing the British Medical Association and six the British Science Guild; and the members of it formed the deputation to Mr. Balfour, with the addition of several members of the House of Commons. Two cardinal proposals were made—first, that medical discoveries, even when made accidentally and not as a result of designed investigation, should be encouraged by direct pecuniary reward; secondly, that for losses or outlays incurred by private investigators engaged in medical discovery the State should recognise the principle of compensation.

These two proposals rest on the fundamental fact that, owing to the peculiar nature of medical service and the necessity for carefully adjusted ethical sanctions, the individual medical investigator has often to sacrifice the welfare of himself and his family, although his investigation may have the highest social value. The capacity for discovery, including invention, is very unevenly distributed, but in every field of science rewards, both financial and honorary, act as powerful evocatives of faculty. In any sphere except medicine, an invention or a discovery has at least a "business" chance of bringing a direct reward, for the investigator can patent his invention or protect himself in some other way. In medicine he cannot patent a new microbe or a new method. The attempts to patent or protect serums or similar products are usually failures, and may end in the removal of a name from the register "for infamous conduct in a professional respect." Probably in this matter the medical profession is too exacting, but there are obvious good reasons for maintaining on the highest ethical level the sanctions of a profession that touch so nearly the private life of the subject. These sanctions, therefore, must continue to be a serious handicap to the medical investigator, who cannot employ the ordinary business methods to secure for himself any profit from his invention, or discovery, or new method of treatment.

If medical discovery is thus shut out from normal commercial reward, there is good ground for the view that the State should establish a system of compensation. To a certain extent, medical research is itself a career, and in the future development of medicine research will offer more and more openings for talent. But meanwhile it is certain that the medical inventor or discoverer has much less chance of making even a respectable living than the clinical medical practitioner. Of this it would be easy to give sufficient proof, but it is not seriously disputed.

Within the medical schools there are many forms of award, such as honorary degrees, money prizes, and the like; but their distribution is largely accidental. Further, the inventor or discoverer has so to specialise his energies that he may positively disqualify himself for the more lucrative administrative or clinical posts. This is more or less true of every branch of applied science, not to speak of pure science; it is overwhelmingly true of medical scientific investigation.

The joint committee and the deputation have uncovered an important scientific area where the State might well recognise a duty to compensate. How profoundly the economic motive operates to increase the production of inventions the Courts for the war awards have abundantly shown. It would be to the ultimate advantage of the State to pay for medical and other scientific discoveries which bring no financial gain to the men who made them: the method of payment is a detail and need offer no more difficulty than that involved in making other awards. The principle is so sound that it ought at once to be conceded.

English Cytology.

An Introduction to the Study of Cytology. By Prof. L. Doncaster. Pp. xiv+280+xxiv plates. (Cambridge: At the University Press, 1920.) Price 21s. net.

THE publication of this volume is to be regarded as an event in the progress of cytology. Prof. Doncaster's new book is not intended to serve as a text-book on cytology, though it contains a wealth of facts; but its aim is to interest the senior student in the subject by pointing out the way in which cytology is related to the great fundamental problems at the root of all biological research. Quite recently Paul Buchner, of Munich, published a new "Handbuch" of cytology, and it is with pride that we compare the work before us with its German prototype. A great deal of the material in Prof. Doncaster's book is new, and the work is as strictly up-to-date as is possible when one is dealing with a vast and changing subject such as cytology.

The author's conception of the cell is very broad; he recognises the important part played by the nucleus, but pays due attention to the Golgi apparatus and mitochondria, which he considers may be of special importance in the life of the cell; useful discussions on the structure of protoplasm, such as are illustrated by Hardy's work, and on Hertwig's conceptions of the "karyoplasmatic ratio," are added to this part of the book. The question of the origin and relationships of the centrosome has been treated in a masterly way, and the author shows how J. W. Jenkinson's work on the fertilisation of the Axolotl can provide a middle way between the divergent views—that centrosomes arise from pre-existing centrosomes, and that they may be formed *de novo* in the cytoplasm.

Prof. Doncaster steers a careful course through the troubled waters surrounding the various questions with regard to astral rays, spindle fibres, and "mitokinetism." He gives a fair and lucid *exposé* of the various ingenious hypotheses brought forward to explain mitotic division, but concludes that, at present at least, no really satisfactory explanation of the phenomenon of mitosis has been given.

Students of cytology are often turned away from entering into the various problems associated with the behaviour of the chromosomes in the germ-cell cycle by the fact that the whole question is obscured by a multitude of ill-digested descriptions, theories, and hypotheses. Prof. Doncaster has written an exceptionally clear and able account of the typical behaviour of the chromosomes. Never polemical, he gives a straightforward account which includes on a broad basis all the mo[illegible] on the chromosomes. His first description of maturation is written with an eye to his later accounts of the chromosomes in sex and Mendelism, but he is careful not to confuse his preliminary survey by bringing in debatable matter. Here the student will find a conveniently introduced *résumé* of the Chiasmatypy hypothesis of Janssens, which has gained such prominence among Mendelians.

The modern work on the behaviour of the cytoplasmic inclusions during spermatogenesis has been the subject of careful descriptions. Prof. Doncaster has treated the matter in an able manner, and the worker unacquainted with the Golgi apparatus and mitochondria will find in this book a readable and accurate account of the present state of our knowledge. The various questions surrounding the formation of egg yolk are not treated at length, and should be included in a future edition; we refer especially to the work of Weigl, Hirschler, Rio Hortega, etc. The author exhibits a commendable scepticism with regard to the specificity of the so-called "chromatin" dyes, and points out in several parts of the book that cytoplasmic bodies unrelated to chromatin may stain basophil, and yet not be true chromatin.

In his chapter on segmentation Prof. Doncaster succeeds in bringing out the fact that we have really proceeded a very short distance in the elucidation of the great problems surrounding even the first stages of animal development. In a later part of the book the author discusses some of these problems.

The subject of parthenogenesis is treated at length, and the author draws freely from his own researches on this fascinating subject. He recognises four main sections with regard to the behaviour of the chromosomes in naturally parthenogenetic animals. We are sorry to see that he has not adopted Sir Ray Lankester's suggestions as to the nomenclature of parthenogenesis. In his treatment of the subject of artificial parthenogenesis Prof. Doncaster points out that there are numbers of problems which are still unsolved with reference especially to the determination of sex. The question of the restitution of a diploid chromosome number in some artificially parthenogenetic animals is also peculiar, and its mechanism ill-understood. A special chapter on the chromosomes in sex-determination has been added, somewhat on the lines of the author's "Deter-

mination of Sex." The peculiar position of Lepidoptera and Aves with regard to these matters is emphasised.

A welcome section on "Germ-cell Determinants" gives clearly the main facts which have been ascertained. The author is commendably cautious in his discussion of this interesting subject, and recognises that "although these bodies are evidently strictly correlated with the germ-cells, there is no absolute certainty that they are the cause of the differentiation of germ-cells from body-cells."

Most cytologists will concur with Prof. Doncaster in his view that the weight of evidence is in favour of the main theory of the individuality of the chromosomes; the author emphasises the fact that the chromosome itself is in all probability divisible into smaller units, which may have an individuality more fundamental than the chromosome as a whole, and he suggests that the individuality theory should be extended so as to regard these granules (microsomes) as the fundamental units.

The chapter on the mechanism of hereditary transmission introduces a discussion on the most recent work on Drosophila and Abraxas. Prof. Doncaster is here dealing with a subject which he has himself studied specially, and though he treats the question with impartiality, he comes to the conclusion that not only does the behaviour of the chromosomes in the maturation divisions of the germ-cells provide the mechanism required for Mendelian segregation of characters, but also that the work of Morgan on Drosophila carries us a step farther and gives us some idea how the groups of characters may be related to special chromosomes. The author recognises the difficulties with regard to our full acceptance of the theories of Morgan and his colleagues relating to the mechanism of "coupling" and "crossing over," but states that no other hypothesis which has been brought forward fits the main facts so well. He concludes his book with an essay on the *rôle* of the cytoplasm in heredity, and gives a good account of the organ-forming substances.

Arranged and written as it is, this book is certain to stir up interest in the subject of cytology. By pointing out the perfections and defects of our present-day basic cytological theories and hypotheses, the author has succeeded in emphasising the lines along which fruitful research may be followed. We hope that this book will mark the beginning of greater activity among English cytologists. Prof. Doncaster is to be congratulated warmly on this excellent work. J. B. G.

Matrices.

University of Calcutta: Readership Lectures: Matrices and Determinoids. By Prof. C. E. Cullis. Vol. ii. Pp. xxiii+555. (Cambridge: At the University Press, 1918.) Price 42*s.* net.

THE history of the mathematical term "matrix" is likely to be very interesting. Its original meaning was an array of symbols (a_{mn}) forming a rectangle of m rows and n columns, out of which determinants were selected by picking out columns (or rows) of the array. A square matrix gives only one associated determinant, but a square matrix is not the same thing as a determinant.

When we change from one set of variables to another by linear relations

$$y_j = \sum_i a_{ij} x_i \quad (i=1, 2, \ldots n; \; j=1, 2, \ldots m),$$

we have an associated matrix (a_{mn}), or A, which is square only when the number of variables is the same in each set. In practice this is the most usual case, and it will be simpler to confine ourselves to this for the present. If we take a new set of variables z_i such that

$$z_j = \Sigma b_{ij} y_i,$$

we have a matrix $B = (b_{nn})$, and by eliminating the symbols y_i we deduce

$$z_j = \Sigma c_{ij} x_i,$$

where the symbols c_{ij} are derived from A, B by a process of "composition," and form a new matrix C. We write $C = AB$ symbolically, and thus start the theory of the multiplication of matrices. There are many analogies with the theory of groups; for instance, BA must be distinguished from AB, multiplication is associative, and so on.

Cayley seems to have been the first to develop the theory of square matrices from this point of view (Phil. Trans., vols. cxlviii., clvi., and elsewhere); other English mathematicians, such as Sylvester, Buchheim, and Tait, took up the subject later on. It may be specially noted that H. Smith's memoir on linear indeterminate equations and congruences contains a great deal of the fundamental theory of matrices, both square and rectangular. In particular, there is a complete and, we believe, original statement of the existence and properties of the elementary factors of a determinant the elements of which are ordinary integers. Weierstrass, Kronecker, and Frobenius, especially the last-named, have made important contributions to the subject.

It will be seen that a matrix is now not merely a scheme of symbols used to specify a set of deter-

minants, but a kind of entity of a very abstract and comprehensive type. A large part of group-theory and many complex linear algebras can be expressed in terms of matrices, and this absorptive property of matrix-theory will probably become more evident in course of time. Matrices occupy a special section in the International Schedule, and the Royal Society Index contains about sixty titles under that heading. Papers under other headings (especially determinants) have also more or less bearing on the subject. Prof. Baker's works on Abelian functions show the importance of matrices in the general theory of theta functions. Some knowledge of the subject is becoming essential in connection with various branches of pure mathematics.

Prof. Cullis's second volume, if we understand the author aright, seems to be a continuation rather different from that which he originally planned. This is not to be regretted, because in this portion we have statements and proofs of well-known and important theorems in the author's own notation, and a large number of illustrative examples. Among the subjects treated are ranks of matrix products and factors, equigradient transformations, certain matrix equations of the second degree, and various properties of a pair of matrices ("paratomy," "orthotomy," and so on). Much of the argument is put into a quasi-geometrical form. The outstanding feature of the work, which the author properly emphasises, is the detailed discussion of rectangular, as distinguished from square, matrices. For this reason alone the work ought to give a great stimulus to the subject, and we hope that the publication of the whole treatise will not be long delayed. Until it is finished, it will be difficult, if not impossible, to give a proper appreciation of it, especially as the author introduces so many new symbols and technical terms. One thing, however, is certain: we now have the outlines of a calculus of matrices in which the operations of addition, subtraction, and multiplication are definite. It may be conjectured that some of the most important applications will be to problems connected with a compound modulus, arithmetical or algebraical as the case may be.

As a matter of curiosity it may be noted that one or two of the very first problems in the theory of rectangular matrices occur in Gauss's "Disquisitiones Arithmeticæ"; for instance, in connection with the theory of composition of quadratic forms, we have the problem of finding a matrix $(a_{2,4})$ the six determinants of which are to be six assigned integers, subject to a certain relation.

G. B. M.

The Chemistry of Animal Products.

The Essentials of Chemical Physiology: For the Use of Students. By Prof. W. D. Halliburton. Tenth edition. Pp. xi+324. (London: Longmans, Green, and Co., 1919.) Price 7s. 6d. net.

THE fact that this well-known and appreciated text-book has reached its tenth edition is sufficient evidence that it satisfies adequately the need for a short practical course in the chemistry of the substances found in and produced by the activity of living tissues. This object is excellently attained. It is not to be expected that a detailed account of the chemical processes occurring during the life and functional action of the organs of the body is to be found therein. Indeed, it would be impossible to separate the chemical from the physical aspects of any of these physiological processes. Such a separation appears to be an unfortunate necessity in a great part of the teaching of the subject, but a more intimate union between the chemical side and what is sometimes called the "experimental" side of the student's work is very desirable, and might be arranged without much difficulty.

There are some important questions which are apt to fall out in the present arrangement; such are those of permeability, osmotic pressure, hydrogen-ion concentration, and the properties of colloidal solutions. In a future edition Prof. Halliburton might find it possible to include a few simple exercises in these problems. An intelligent grasp of the principles involved is not to be attained by the mere reading of statements about them, while even a small number of experiments have great value. On account of its importance in physiological phenomena, some experiment showing the synthetic aspect of the action of enzymes might well be inserted.

A general criticism which applies to most text-books on practical chemistry, especially to those on biological chemistry, is that a number of the tests given suggest cookery recipes rather than scientific experiments. A student is very little the better for performing Molisch's sugar test if he is ignorant of what the result is due to. And how many understand, when they make the tests, why some sugars reduce copper salts, while others do not; or why tartrates are added to Fehling's solution? It would often be better to curtail the recital of what is to be found in general text-books in order to explain the reasons for the results of the actual experiments made.

In the book before us the theoretical part is, on the whole, brought well up to date. In view of

recent work, however, the statements with respect to anti-enzymes might well have been more critical. Some of us might demur to the statement on p. 83 that margarine-makers have learned to make this fat palatable. W. M. B.

Physics: Theoretical and Practical.

(1) *A Handbook of Physics Measurements.* By Ervin S. Ferry, in collaboration with O. W. Silvey, G. W. Sherman, jun., and D. C. Duncan. Vol. i. *Fundamental Measurements, Properties of Matter and Optics.* Pp. ix+251. Vol. ii. *Vibratory Motion, Sound, Heat, Electricity and Magnetism.* Pp. x+233. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1918). Price 9s. 6d. net each vol.

(2) *Notes on Magnetism: For the Use of Students of Electrical Engineering.* By C. G. Lamb. Pp. viii+94. (Cambridge: At the University Press, 1919.) Price 5s. net.

(1) IN the two volumes forming "A Handbook of Physics Measurements" are given the theory and manipulation of those experiments which experience has shown to be most important in pure and applied science. The work is designed for college and industrial laboratories, and forms a self-contained manual. Each chapter consists of two parts; the first includes definitions, a description of the apparatus, and the general theory of the methods, while in the second each determination is described in detail, the more important sources of error are pointed out, and means are indicated by which these errors may be minimised or accounted for. Most of the experiments require no mathematics beyond trigonometry and algebra, but the authors have rightly decided to employ the calculus methods wherever these would result in economy of time and mental effort.

No student except one specialising in physics would perform all 108 experiments included in the two volumes. Other students, after performing the necessary experiments on the properties of matter, would limit themselves to the groups bearing directly upon their principal study. Thus the chemist would do the work on indices of refraction, using various forms of refractometer, such as the Pulfrich, the Zeiss, the Abbe, the Féry, or the more recent instrument designed by Dawes. He would also make use of spectroscopes and spectrophotometers, and learn that "spectrocolorimetry"—the estimation of the concentration of solutions by means of the intensity of the absorption bands of their spectra—is a method which may be both more speedy and more precise than chemical analysis. The electrical engineer would do the work on damped vibration and harmonic analysis, in addition to the usual experiments on the determination of resistances, capacities, or inductances. The mechanical engineer will be interested in the methods for the determination of the economy effected by steam-pipe coverings and of the thermal value of both coal and gas. The work as a whole is to be recommended as giving a thoroughly up-to-date account of most of the important physical instruments and experimental methods.

(2) For the use of students in the engineering laboratory, Cambridge, Mr. Lamb has drawn up a convenient set of notes dealing with the essential parts of the subject of magnetism. Starting with fundamental facts and principles, such portions of magnetic theory are outlined as are required in order to read the ordinary technical text-books with intelligence. The work has been well done, and the latter part of the book, dealing with magnetic hysteresis and alternating-current tests, will be of special service to both students and teachers, who will welcome the admirable diagrams and the lucid descriptions. H. S. A.

Minerals and Metals.

(1) *Zinc and its Alloys.* By Dr. T. E. Lones. (Pitman's Common Commodities and Industries. Pp. ix+127. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 2s. 6d. net.

(2) *Asbestos and the Asbestos Industry: The World's Most Wonderful Mineral and other Fireproof Materials.* By A. Leonard Summers. (Pitman's Common Commodities and Industries.) Pp. ix+107. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) Price 2s. 6d. net.

(3) *Tin Ores.* By G. M. Davies. Pp. x+111.

(4) *Manganese Ores.* By A. H. Curtis. Pp. x+118. (Imperial Institute: Monographs on Mineral Resources, with Special Reference to the British Empire.) (London: John Murray, 1919.) Price 3s. 6d. net each.

THE first two of these little books are two of the volumes in a series issued with the object of giving general readers an account, in language as untechnical as possible, of the origin, mode of production, and uses of a number of the essential articles employed in industries. The object is an excellent one, for it is knowledge of a kind that the user and even the merchant of these materials rarely possess, though the advan-

tage of having such information is sufficiently obvious.

(1) The volume on zinc is an excellent example of what such books ought to be; it gives, first, a brief history of the metal, then a description of the various ores from which it is extracted, and of the processes employed in dressing these ores or rendering them marketable, including, it may be noted, a very fair summary of the modern flotation processes. The next chapters give a good and quite up-to-date account of the methods employed in smelting the metal or extracting it from the ores, and a final chapter is devoted to the alloys of which it forms an important constituent. It is a pity that the author did not keep clear altogether of chemical equations, which he might easily have done in a purely popular treatise, as he has been somewhat unfortunate in their use; it is difficult to understand how he ever came to write such an equation as

$$2ZnS + 2O_2 = Zn_2 + 2SO_2,$$

for the context shows that he knows well enough that no such reaction ever takes place. Again, he would have done better to omit the equation $2ZnO + 2CO = Zn_2 + 2CO_2$, because although oxide of zinc can be reduced by carbonic oxide, the reaction can take place normally only in the presence of excess of carbon, which at once again reduces the carbonic anhydride to carbonic oxide. The author's equation would suggest that carbonic anhydride is evolved in the process of zinc smelting, whereas, in fact, the evolved gases consist almost entirely of carbonic oxide. In a future edition the author might with advantage devote a little space to the galvanising of iron, seeing that about half the world's production of zinc is used for this process.

(2) The volume on "Asbestos" decidedly suffers by comparison with its companion volume, as the author does not take care to avoid a number of errors, which, though common enough in the trade, ought not to find their way into a book of this description. He does not by any means make it clear, as he should have done at the outset, that the trade name "asbestos" is applied to several different minerals; the name was apparently given originally to tremolite, actinolite, and other varieties of amphibole, but it is also applied to fibrous forms of pyroxene, to the very different mineral crocidolite, distinguished by the large proportion of ferrous iron that it contains, and, lastly, to chrysolite, a fibrous variety of serpentine, which differs from all the foregoing in that it is a hydrated silicate, whereas all the others are anhydrous. Again, no serious work should contain such statements as: "Next to coal, asbestos is now undoubtedly the most important of the non-metallic mineral products of the world," or "older than anything in the animal or vegetable kingdom"; surely the author cannot suppose that asbestos is of more importance than salt, for example, and surely he would not question the inclusion of, say, Silurian trilobites in the animal kingdom. His statement that the works of the United Asbestos Co., Ltd., at Harefield, Middlesex, are alongside a coal-pit is unintelligible; there are certainly no collieries in that part of England. When he deals with the manufacture of asbestos into cloth, yarn, packing, boiler coverings, and the numerous patented materials of which it forms an essential constituent, he is on safer ground, and supplies much useful information in a convenient form.

(3) and (4) The Imperial Institute is doing excellent service in issuing the handy monographs on the mineral resources of the British Empire, two of which have recently appeared. There is, of course, nothing new in either of these works, they being careful compilations of well-known information and statistics; this does not imply that the production of such compilations is at all an easy task, or that the compiler has not done good service in carrying it out. On the contrary, the collection of the large mass of material which has here been brought together requires a laborious and painstaking search through many and various sources of information, not all of which are readily accessible to the general reader, as a glance at the very useful bibliographies appended to both volumes will at once show. In one respect the two mineral substances discussed in the respective volumes show a marked contrast: workable tin ores occur in relatively few localities, whilst ores of manganese are very widely distributed, and to be found in most parts of the world, although it is true that large deposits of manganese ores are far from plentiful; but in other respects the tasks of the authors have been very similar.

The general scheme of both books is identical. The first chapter is devoted to the uses and applications of the metal and its compounds, and to the nature and general characters of the ores; the second deals in some detail with the occurrences of the ores within the British Empire; and the third reviews briefly the main sources of supply in other parts of the world. In both cases the work has been carefully and thoroughly done, and the handbooks may be looked upon as giving trustworthy information upon the subjects treated in a compact and convenient form.

Our Bookshelf.

The Engines of the Human Body: Being the Substance of Christmas Lectures Given at the Royal Institution of Great Britain, Christmas, 1916–1917. By Prof. Arthur Keith. Pp. xii+284+ii plates. (London: Williams and Norgate, 1919.) Price 12s. 6d. net.

WORKS on physiology commonly appeal either to the usual types of student, or else to those engaged in teaching or research work. The work before us claims to appeal in the first place to the general reader "who desires to know what modern medical teachers think of the marvellous contrivances of the human machine." The title of the book, with the foregoing quotation, indicates the spirit in which the author has approached the subject. Prof. Keith's fertile imagination has sought analogies between the various functions of the organs on one hand, and divers mechanisms of human design on the other, and he certainly never seems at a loss for them. In so far as the general reader has no previous knowledge of the subject, the method of treatment by analogy alone seems calculated to give rise to an abundant harvest of grotesque misconceptions, as all those who have taught elementary physiology are well aware; but the book should be truly welcome to a teacher who, while having some acquaintance with the subject, is yet lacking in the knowledge or imagination necessary to evolve instructive analogies to help to fasten in the pupil's mind what he wishes to impart.

Many of the mechanical analogies are quite new and should be worth adopting, but others seem superfluous or misleading; for example, the comparison of muscular tissue with an internal-combustion engine is a sound and generally recognised conception, up to a certain point; but to refer to tendons as "piston cords," or to arteries and veins as supply and exhaust pipes, is pushing a good analogy to the point of whimsicality. For the first thirteen chapters, however, in spite of this, the reader should go along smoothly enough, but after this point, when analogies fall thick as autumn leaves, the general reader is likely to lose sight of the track. There are some inexactitudes in the book which do not fall in the category of bad analogies; for example, the statement that the velocity of the nerve impulse is four miles a second, that nerves are "living and pulsating," and that nerves are subject to fatigue (p. 263). The historical fragments which are frequently introduced are of considerable merit, partly on account of the relief experienced by the reader in meeting plain, unveiled fact, but chiefly because they are exceedingly well chosen.

C. L. E.

A Class-book of Organic Chemistry. By Prof. J. B. Cohen. Vol. ii.: For Second-Year Medical Students and Others. Pp. vii+156. (London: Macmillan and Co., Ltd., 1919.) Price 4s. 6d.

THE average medical student is inclined to regard chemistry as a subject which has to be studied in order to pass certain examinations, and having passed these, he dismisses the subject from his mind. This is in large measure due to the fact that the text-book he has come across has failed to stimulate his interest, and the probability is that he will get rid of the book at the earliest opportunity.

The little volume under review, however, is one that we venture to think the student will not be likely to part with, as it gives a very clear, concise, and readable account of the subject, which may stand him in good stead in his future studies; it is divided into ten chapters, as follows: Synthesis, The Oils and Fats, The Carbohydrates, Some Natural Organic Bases, The Pyrimidine and Purine Groups, The Proteins, Fermentation and Enzyme Action, The Essential Oils, The Alkaloids, and Synthetic Drugs. Each of the sections is thoroughly up-to-date, and we know of no book which, within so small a compass, deals with such varied subjects as, for example, the Grignard reaction, the synthesis of disaccharides, the origin of uric acid in the animal organism, and the theory of alcoholic fermentation, besides giving the constitutional formulæ, so far as they are known, of yeast-nucleic acid, hæmin, ætiophyllin, and the more important alkaloids, such as strychnine and morphine. The last chapter, in addition to giving the constitution of many of the better-known synthetic drugs, contains a short account of the more recent antiseptics, such as chloramine-T, and the dyestuffs malachite green, acriflavine, etc., as well as a brief sketch of the trypanocidal action of the organic arsenic compounds.

The first volume, published in 1917, was meant to serve as an introduction to organic chemistry, and the two volumes together can be thoroughly recommended as a most excellent and handy little compendium, which should find great favour among students and teachers alike.

Examples in Electrical Engineering. By J. F. Gill and F. J. Teago. Pp. 173. (London: Edward Arnold, 1920.) Price 7s. 6d. net.

A BOOK of this kind, which consists of a collection of model examination papers, followed by model replies, should be not without its uses to those who are obliged to study the art of passing examinations, as well as the principles of electrical engineering, as a careful perusal of its contents will enable the student not only to practise his knowledge of the various parts of the subject, but also to form good habits in the way of presentation of the solution of the problems in a clean form and logical sequence. The drawing of good diagrams and the frequent use of graphical methods are very rightly insisted on, and admirable conciseness is observed. The papers cover both "intermediate" and "advanced" standards, and relate on the whole to practical applications, rather than to theory.

Letters to the Editor.

The Plumage Bill and Bird Protection.

AT the present time there is a measure before the House of Commons known as the Importation of Plumage (Prohibition) Bill, the object of which is "to prohibit the importation of the plumage of birds and the sale or possession of plumage illegally imported," excepting the plumage of ostriches and eider ducks, but "the prohibition or importation imposed by the Act shall not apply to any plumage imported in the baggage or as part of the wearing apparel of a passenger." The Bill further provides for the granting of a licence, subject to certain conditions and regulations, authorising the importation of plumage for natural history museums, for the purpose of scientific research, or for any other special purpose.

In connection with this measure numerous conflicting interests are threatened and grave misunderstandings exist, due very largely to lack of knowledge of the actual facts. Whilst yielding to no one in my love of wild birds and all the æsthetic interests associated with wild-bird life, I cannot shut my eyes to the fact that a considerable amount of sentimentalism, misrepresentation, and exaggeration has been put forth by supporters or well-wishers of this measure, and similarly by the opposers respecting trade losses, the extent of the employment the trade ensures, the absence of cruelty involved in the trade, etc. Neither of these views helps us to understand the situation or calmly and dispassionately to form an unbiassed opinion, for both of them are far from the actual truth.

There is now ample evidence to show that a considerable trade is done in the plumage and skins of wild birds which are largely utilised for the decoration of women's hats, etc. In different centres, such as London, Manchester, Paris, Berlin, Vienna, and elsewhere, this trade affords employment to a number of workers. The "horrors and barbarities of the traffic" have been luridly described by one set of writers and denied by another. Without accepting either of these sets of exaggerated statements, information in my possession shows that gross cruelty is frequently committed. Prof. E. H. Forbush states that brutal savagery is characteristic of this phase of bird destruction, and points out that this "has been well illustrated in the extermination of the egrets of the United States." No unprejudiced mind can exonerate or satisfactorily explain away this highly objectionable side of the question.

Of the species of birds sought after, we are constantly being assured that they are injurious, that they are "as common as rooks," or that we do not possess any exact information as to the effect this trade has had upon their numbers. The fact is that the majority of the species are beneficial so far as agriculture or horticulture is concerned, and only a very few injurious. There is exact and incontrovertible evidence that where thirty-five or forty years ago millions of birds existed, they are now practically extirpated. A single "rookery" of egrets was estimated by a well-known ornithologist to contain three million birds in 1878; in 1888 they were rare, and in 1908 almost extinct.

It is pointed out by supporters of this Bill that prohibition laws exist in America, Australia, India, and elsewhere, but it is not mentioned that, in the opinion of many competent judges, in consequence of such laws certain beneficial species of birds have suffered and injurious ones unduly increased.

Again, it has been suggested that such birds as egrets might be cultivated in natural reserves, and their plumes or "aigrettes" collected as the birds moult. The most perfect of such feathers, so we are informed, fetch as much as 2*l.* apiece. That the farming of these birds is a practicable scheme is proved by the fact that the National Association of Audubon Societies in the United States has established such a colony on a small island in the Stono River, near Charleston, and in 1917 it was tenanted by more than four hundred birds. Again, on Avery Island, Louisiana, U.S.A., there is a "rookery" of snowy egrets which in 1916 was carefully examined by Prof. J. S. Huxley, and reported to contain between eight and nine hundred nests. It may be well, perhaps, to remind the advocates of such schemes that, like all members of the family Ardeidæ, herons and egrets subsist very largely upon fish, and there is little doubt that the establishment of a series of large rookeries would have a disastrous effect upon fresh-water fisheries.

Whilst in no manner advocating opposition to this Bill, we must face the question: Supposing that it is placed upon the Statute-book, shall we have done anything to stop the trade in the skins and plumage of wild birds? Personally, I have grave doubts whether the object desired can be obtained by this measure. As an Act of Parliament its example and influence may be for good, but it will certainly not put a stop to the plumage trade. It must be realised that if we prohibit this trade in London, it will still flourish in Paris, Berlin, and elsewhere. The Bill will simply move the venue of the market; it will not bring about a smaller demand. To put an end to this we must educate the public, not by giving currency to wild and often inaccurate statements, but by teaching the rising generation "to view the question of the preservation of wild-bird life from a higher and much truer standpoint than heretofore. That wild birds have a utilitarian value no one can deny, but they also have an æsthetic value far outweighing all others. . . . Surely the general public have some rights where beautiful natural objects are concerned. . . . Posterity will undoubtedly regard us—and who shall say not rightly?—as stupid people, dull of apprehension and procrastinating in nature, in that we have permitted various species of wild birds, one after another, to disappear from our land; and our children's children will rise up and ask why we did not secure to them the natural pleasures which their forefathers could have enjoyed had they had eyes to see with and minds tuned beyond the din and bustle of the highways and byways of commerce" (*National Review*, 1920, p. 95).

Whilst the decoration of the person with wings and feathers may be regarded as the vulgar and depraved fancy of a day, the fact cannot escape us that there is a large section of the general public who are willing to pay high prices for these goods; and so long as this demand continues, so long will a supply be forthcoming.

By making the Plumage Bill a law of the land we can say that in this country we will have nothing to do with the trade and that it shall be prohibitory to carry on the trade in the United Kingdom. That it will have any effect on the destruction of wild-bird life, however, is certainly most unlikely. A plentiful supply

of the goods will be forthcoming so long as a demand exists, but once it is regarded as offensive—or shall we say indicative of a lack of good taste?—to wear such things as the wings, heads, feathers, or bodies of birds, the demand will cease and the trade, so far as this country is concerned, disappear. Herein we think, lies a remedy far more effective than any Act of Parliament. WALTER E. COLLINGE.

The University, St. Andrews, March 27.

The Physiology of Migrations in the Sea.

THE flat-fishes of Northumberland in the immature condition migrate more or less inshore in summer and offshore in winter. Flounders are relatively static, plaice migrate offshore to the north-east and dabs to the south-east. The migration is not, as a rule, conspicuous, and, so far as the young stages are concerned, might be regarded as not taking place.

With approaching maturity, however, these three species migrate far to the north. The flounders for the most part reach the coast of Fife, and the plaice deeper water off the Forth and the Scottish coast to the north. The dabs do not appear to migrate so far to the north as the plaice, but we have a record of one that migrated so far as St. Andrews Bay. Fulton has shown that the Moray Firth plaice migrate to the north, and even to the Atlantic.

The migrations may be said, therefore, to be a series of seasonal inshore and offshore movements, followed by a marked contranatant journey for spawning. After spawning the spent fish resume the seasonal migrations, and become then, more obviously, summer inshore migrants.

We have thus plainly two factors at work: one external, which may be associated with temperature, the other internal, which we at once conclude to be due to the action of an internal secretion. The seasonal migrations are obviously independent of the spawning migration, and may be said to be produced by hydrographical conditions and the contranatant ability of the fish. Under the influence of the spawning impulse fish migrate usually to a great, and sometimes to an immense, distance. The effect is strong enough to force the eel to descend from fresh water to the sea, and thence to mid-ocean, and to impel the salmon from the sea to the river, and, in spite of difficulties, to the spawning-ground.

The spawning migration is not always so plainly marked, but these considerations go to show that all fish migrations are of a similar character, a general seasonal series of movements affecting all, and a special migration under the dominating influence of an internal secretion or hormone, which, proceeding from the developing gonad, is carried by the blood to the nervous system. With reference to the species referred to above, it can be said that the hormone begins to exert its influence about autumn or the later months of the year, and continues its effect during the whole period of ripening. It is periodic in its manifestations, and the call, when it comes, is imperative. Only in special circumstances, as lack of water, say, in the river, can the spawning migration be said to be modified by hydrographical or other physical conditions. The distinction between the two kinds of migration must be clearly kept in view if we are to understand and appreciate the results of marking experiments. From, say, November to the spawning season mature plaice are contranatant migrants; after spawning they are denatant, or usually so, until the winter. The large number of records which have been accumulated, resulting from the investigations of past years, should be reconsidered with this in mind.

It is interesting to observe that the only invertebrate of the migration of which we have direct proof behaves almost exactly like the plaice and the flounder. The common edible crab (*Cancer pagurus*) migrates inshore in summer and offshore in winter with the greatest regularity. Maturity impels the female to become a contranatant migrant. The females migrate from the Northumberland coast to the southern coast of the Firth of Forth, some of them still further to the north, even to the Moray Firth, the general results indicating a direct relationship between size and distance. The hormone is therefore secreted in the crab by the developing ovary, and it reacts in exactly the same way as that of the fish. The experiments have clearly proved that the migration does not occur until the winter before the season of spawning, and in this respect the crustacean and the fish are in agreement. It takes place during the offshore winter migration and in deep water, but the effect is differential, the male not migrating. It is not necessary for the male to migrate, as the migration takes place after pairing, even a year or two years after. This appears to indicate that the internal secretion is under control or may be withheld in response to evolutionary necessity.

Dr. Gurley, in the *American Journal of Psychology* (1902 and 1909), brought under review the indications of the intoxication of the central nervous system by internal secretions as explaining the spawning migrations of fresh-water fish in North America; so that the point is not new. We do not know very much about the internal secretions, but we know enough to be able to say that they act directly and quickly as an intercommunication between organs with or without reference to the nervous system. In the sea the effects are indicated by migration in the case of such animals as are capable of making migrations, but it is obvious that in many cases the internal secretions derived from the gonad have somatogenetic as well as mental effects, as in the development of secondary sexual characters.

The developing gonads of fish and the crab offer interesting material for the investigation of internal secretions by a biochemist. My main object, however, is to indicate that we already know the general facts and laws of migration, that marking must be done intelligently and the results read with due consideration of the laws, and more especially that the spawning migration is due to an intoxication of the central nervous system, and brings about a migratory result independent of temperature, salinity, and every other hydrographical condition.

ALEXANDER MEEK.

Armstrong College, Newcastle-upon-Tyne, March 30.

Muscular Efficiency.

WHEN muscular force is exerted, power is expended and fatigue is produced, even when the muscle remains stationary. Again, when no external force opposes the contraction of the muscle, physiological causes set a limit to the speed at which contraction can take place. In both cases the whole power expended is lost in so far as the production of useful work is concerned. When there is no velocity the power is used in maintaining the stress, and when there is no resistance, in maintaining a constant velocity.[1]

In all ordinary muscular operations both these sources of power leakage act simultaneously but in

[1] This loss is independent of any power lost in the acceleration of the parts.

different degrees, and it becomes a definite problem to determine for any muscle or combination of muscles the relation between the speed of muscular contraction and the muscular force which will yield the greatest external power. The problem may be solved by means of the diagram in Fig. 1.

It is assumed that the muscular machine has a constant output of power which is represented by the product xy (x pressure, y velocity) of the co-ordinates of the hyperbola AB. Also, that the pressure available for producing exterior power is less than x by some quantity $\psi(y)$ depending on the velocity, and represented in the figure by the abscissa of the curve DD′, the effective velocity in the same way being less

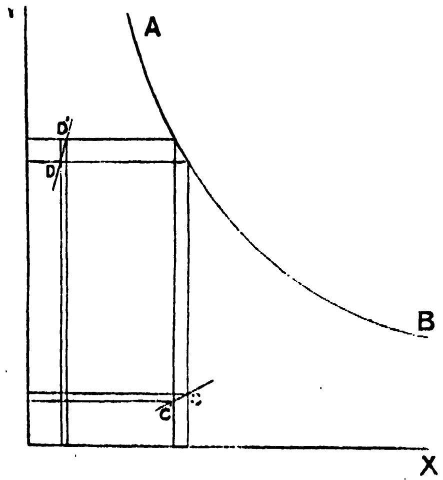

Fig. 1.—X, Y, co-ordinates of hyperbola AB. $\phi(x)$, ordinates of CC′. $\psi(y)$, abscissa of DD′.

than y by some quantity $\phi(x)$ depending on the pressure, and represented by the ordinate of the curve CC′.

The useful power is evidently $(x-\psi(y))(v-\phi(x))$, and the loss of power is $x\phi(x)+y\psi(v)-\phi(x)\psi(y)$.

If the co-ordinates for $x+dx$ and $y+dy$ are drawn as in the figure, it is plain that the loss is a minimum (and the useful power, therefore, a maximum) when $(x-\psi(v))d\phi(x)+(v-\phi(x))d\psi(y)=\psi(y)\,dy+\phi(x)dx$.

I know of no experiments which would determine the form of the functions ϕ and ψ—that is, what power is lost in sustaining a load or in keeping a uniform speed. Both these subjects are worthy of investigation, and, with the facilities offered by some

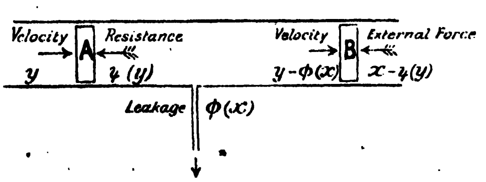

Fig. 2.

of the modern laboratories, ought not to present any great difficulties.

If $\phi(x)$ and $\psi(y)$ were simply proportional to x and y, the most economical speed would make, if $\phi(x)=ax$ and $\psi(v)=by$, $y/x=b/a$; and if $a=b$, the most economical speed would be the mean between that where $\psi(y)=x$ and $\phi(x)=y$.

In reality, however, $\psi(y)$ is, I believe, much less than $\phi(x)$, but this remains for experimental determination. It may be noticed that as $\psi(v)/\phi(x)$ decreases, the most economical speed increases.

A close analogy to the conditions of the problem may be found in a fluid contained between two pistons A and B (Fig. 2), between which there is a leak governed by the fluid pressure. A constant power urges A towards B, and A itself is subject to a frictional resistance depending on its speed. The useful work is represented by the velocity of B against an exterior force, while the leak stands for $\phi(x)$ and the frictional resistance of A for $\psi(y)$.

A. Mallock.

A Dynamical Specification of the Motion of Mercury.

If we assume that the modified Lagrangean function for two mobile and massive particles is of the form

$$L=\tfrac{1}{2}m_1(\dot{x}_1^2+\dot{y}_1^2+\dot{z}_1^2)+\tfrac{1}{2}m_2(\dot{x}_2^2+\dot{y}_2^2+\dot{z}_2^2)$$

$$+\frac{\gamma m_1 m_2}{r}\left[1+\frac{\lambda}{C^2}\left\{(\dot{x}_1-\dot{x}_2)^2+(\dot{y}_1-\dot{y}_2)^2+(\dot{z}_1-\dot{z}_2)^2\right\}\right]$$

where the symbols have the usual meaning, C being the velocity of light and λ a pure number, then the principle of least action $\delta\int L\,dt=0$ leads to the following conclusions:

(1) The motion of the centre of mass is constant.

(2) The orbits of the two particles about their centre of mass are similar and similarly described plane curves, and independent of the motion of the centre of mass.

(3) For the orbital motion the modified Lagrangean function is:

$$L^1=\tfrac{1}{2}\frac{m_1 m_2}{m_1+m_2}\left\{1+\frac{2(m_1+m_2)\lambda\gamma}{rC^2}\right\}(\dot{r}^2+r^2\dot{\theta}^2)+\frac{\gamma m_1 m_2}{r}$$

Hence the equations:

$$\left\{1+\frac{2(m_1+m_2)\lambda\gamma}{rC^2}\right\}(\dot{r}^2+r^2\dot{\theta}^2)-\frac{2\gamma(m_1+m_2)}{r}=\text{const.}$$

$$=-\frac{\gamma(m_1+m_2)}{a}$$

and $$\left\{1+\frac{2(m_1+m_2)\lambda\gamma}{rC^2}\right\}r^2\dot{\theta}=\text{const.}=h$$

Writing $r=1/u$, we have:

$$\left(\frac{du}{d\theta}\right)^2+u^2=\frac{2\gamma(m_1+m_2)}{h^2}\left(u-\frac{1}{2a}\right)\left\{1+\frac{2(m_1+m_2)\lambda\gamma u}{C^2}\right\}$$

From this we may deduce

$$\frac{d^2u}{d\theta^2}+u\left\{1-\frac{4\lambda}{C^2}\frac{\gamma^2(m_1+m_2)^2}{h^2}\right\}=\frac{\gamma(m_1+m_2)}{h^2}\left\{1-\frac{\lambda\gamma(m_1+m_2)}{C^2 a}\right\}$$

or the solution in the form

$$u=\frac{1}{l}\left\{1+e\cos(\mu\theta+\eta)\right\}$$

where $$\mu^2=1-\frac{4\lambda\gamma^2(m_1+m_2)^2}{C^2h^2}$$

These equations are exact.

In applying this argument to the observed apsidal progress of the planet Mercury, it is to be noted that the interpretation of a and h differs slightly from what it would be if λ were zero; but to a sufficient degree of

approximation we find that the apsidal progress per revolution is

$$\frac{4\pi\lambda\gamma^2(m_1+m_2)^2}{C^2h^2}$$

The observed value requires that λ should be nearly $3/2$, and if $3/2$ is taken, we get the result obtained by Prof. Einstein by his new specification and principles.

It may be observed that the above specification by the Lagrangean function could be generalised for any number of particles, and that it involves no departure from recognised dynamics or the normal views of space and time. It does, however, involve the conclusion that the interaction of bodies through the æther, vaguely called "gravitation," is to a very slight degree not exactly in accordance with Newton's specification. Whether such conclusion is really necessary seems still matter of doubt.

I have not seen any discussion of the problem of two bodies on Prof. Einstein's specification, but it appears to me that an exact determination of the relative orbit when m_1 and m_2 are comparable quantities is very desirable. GEORGE W. WALKER.

Portsmouth, March 29.

The Construction of a Magnetic Shell Equivalent to a Given Electric Current.

ACCORDING to Ampère's theorem, the magnetic field due to an electric current flowing in any circuit is equivalent at external points to that due to a simple magnetic shell the bounding edge of which coincides with the conductor, and the strength of which is equal to the strength of the current.

It is generally understood that any surface having the circuit as its boundary will serve as the surface of an equivalent magnetic shell, and the fact that there is a restriction on the nature of the surface does not appear generally to be recognised.

Thus, for example, in Maxwell's treatise (vol. ii., p. 142) we find the following:—"Conceive any surface S bounded by the circuit and not passing through the point P"; while further on he says: "It is manifest that the action of the circuit is independent of the form of the surface S, which was drawn in a perfectly arbitrary manner so as to fill it up."

I propose to show by means of a simple example that the surface is not drawn in a "perfectly arbitrary" manner.

Consider a narrow, rectangular strip of paper the opposite edges of which we shall denote by a and b, its opposite faces by A and B, and its two ends by 1 and 2. We shall represent the ends of the edges by a_1, b_1, a_2, b_2, where the suffixes refer to the corresponding ends of the strip. Now let one end of the paper be turned round through an angle π and joined on to the other end, so that a_1 is joined to b_2 and b_1 to a_2.

Then, since a_1 is joined to b_2, the edges a and b form one continuous line, and, since b_1 is joined to a_2, this line forms a closed circuit.

Thus we may bend a wire into the form of the edge, and can imagine an electric current to flow in it.

Although the electric circuit has the form of the edge, yet we could not have a simple magnetic shell the surface of which was that of the paper.

This is easily seen, for since, in addition to the edges, the faces A and B have also become continuous one with the other, we can no longer distinguish one as positive and the other as negative. The same thing is seen if we try to imagine the surface divided up into elementary portions, in the manner conceived of by Ampère, with a current equal in strength to the given current flowing round the boundary of each.

It is easily seen that Ampère's construction fails for such a surface, which is known to mathematicians as a Möbius sheet.

Although the surface we have described would not serve as the surface of a simple magnetic shell equivalent to an electric current flowing round its boundary, yet it is possible to construct other surfaces having this boundary which would serve as surfaces of equivalent magnetic shells.

If we have one suitable surface we can obtain any number of others from it by continuous deformation while the edge remains fixed.

It is, therefore, desirable to give a general method of constructing a magnetic shell equivalent to a given electric circuit. The following appears to give a surface having the required property:—

Let O be a fixed point external to the circuit, and let P be a variable point. Let P travel once completely round the circuit, so that the radius vector OP traces out some conical surface.

The portion of this conical surface containing O and bounded by the circuit might then be taken as the surface of the equivalent magnetic shell.

In the particular case of the circuit we have considered (as well as in many others) the surface will cut itself, but will, nevertheless, have two distinct faces, one of which may be taken as positive and the other as negative. It thus appears to satisfy the necessary conditions. A. A. ROBB.

March 30.

Volcanic Rocks in the Anglo-Egyptian Sudan.

IN connection with Prof. J. W. Gregory's reference in NATURE of February 19, p. 667, to the discovery of the Bayuda volcanic field, and Mr. Campbell Smith's record of a riebeckite-rhyolite which constituted a number of stone implements found at Jebel Katul, in Northern Kordofan (*ibid.*, February 26, p. 693), some further notes may be of interest.

The rock collected by Sir Herbert Jackson at Merowe is a basaltic scoria, and the specimens either float or just sink in water. A few crystals of olivine are visible to the eye, and, under the microscope, a regular basaltic ground-mass, including felspar, iron ores, and probably glass, can be recognised in the powdered rock. The specimens have evidently been transported by a stream system which drains from the south-east and debouches on the river at the spot where they were found. Save for the neighbourhoods of the river and a few routes by which travellers avoid the long journey around the Abu Hamed bend of the Nile, the maps of the Bayuda Desert are almost blank. Near one of the routes a surveyor has recorded "Hosh Eddalam, crater," and the name means a dark enclosure. Some of the older travellers mistook ironstone concretions for volcanic bombs, and as the surfaces of many rocks are darkened in the desert such a record of a crater did not call for particular note until evidence of extrusive rocks appeared. It is situated in latitude 18° 20′ N., longitude 32° 31′ E., and consequently lies to the west of the route taken by Dr. Chalmers Mitchell. The volcanic field seen from the air probably does not lie on the established routes, as it would certainly have been referred to in reports, even if it were not described. Presumably there can be no doubt about the existence of craters seen by an observer such as Dr. Chalmers Mitchell, but the results of an examination on the ground will be of interest, even if only to know the types of rocks involved.

Mr. Stanley C. Dunn records the presence of rhyolites and felsites near Jakdul, and these are doubtless

similar to those of the Sixth Cataract, about forty miles north of Khartum, where the volcanic rocks are certainly older than the Nubian Sandstone. In the northern parts of Dongola basalt intrusions occur in the Nubian Sandstone, and there is a hot spring at Akasha, about eighty miles south-west of Halfa. Turning to more distant regions, one of the solitary landmarks on the White Nile is Jebel Ahmed Aga, in latitude 11° N., consisting of the remains of a volcanic cone formed of basaltic scoria and evidently of comparatively recent age. Towards the east there are the plateau basalts of Abyssinia, with outliers extending into the Sudan. Along the Langeb Valley, north of Kassala, there is an interesting suite of acid and intermediate volcanic rocks, but we are still in doubt about their age. Similar rhyolites certainly occur farther north among the Red Sea hills. The western parts of Kordofan have been traversed geologically without revealing the existence of volcanic rocks on the continuation of the line referred to by Mr. Campbell Smith. Farther west Darfur appears to be full of recent volcanic rocks, principally of scoriaceous types.

The N.E.–S.W. features seen by Dr. Chalmers Mitchell may have been to some extent due to erosion by sand driven from the N.N.E. by the prevalent wind. The direction of strike among the metamorphic rocks is another factor to be borne in mind. It is not constant over these large areas, but it is very often N.E.–S.W., and would then account for some of the features seen from the air. In these circumstances caution appears desirable in basing wide structural theories on rather scanty data.

G. W. GRABHAM.

The FitzGerald-Lorentz Contraction Theory.

IN the discussion on relativity at the Royal Society on February 5 (NATURE, February 12), Mr. Jeans stated that the FitzGerald-Lorentz contraction theory presented grave difficulties in the case of a wheel rotating about a fixed axle, so that the circumference would contract while the radius would not. Surely these difficulties are not so grave as would appear at first sight? Let us adopt the point of view of the old-fashioned non-relativist to whom space is rigid and Euclidean, even though his measuring instruments may change and so introduce errors in his measurements. A scale is not a rigid invariable unit of length. Its length, even if its orientation is unchanged, depends on its temperature and the tensile or compression stresses to which it is subjected. If we change its temperature, keeping the stresses constant, its length (as measured by a standard scale at fixed temperature) varies. But we may, by suitable means prevent the variation of length, in which case the change of temperature will cause a change of stress. Similarly, on the FitzGerald-Lorentz theory, turning the scale to a different orientation relative to the supposed æther stream causes a change in the electric forces to which the cohesion of the molecules is ultimately due, so that if the temperature and the external stresses remain constant, the length changes. In this case, however, we cannot detect the change directly, as it would be necessary to turn our standard scale also, and it, too, would change. If for any reason the change of length is prevented, the FitzGerald-Lorentz effect causes a change of stress.

Now in the case of the rotating wheel the ratio of the circumference to the radius must remain constant, so that any tendency of one to change its dimensions will affect the other, with the result that both circumferential and radial stresses will be set up, and any changes of length caused must be compatible with the constancy of π. These stresses would in any actual case be almost vanishingly small compared with those due to centrifugal force, so that the only effect of the FitzGerald-Lorentz contraction would be to alter the latter stresses to an utterly negligible extent.

Moseley Memorial.

THE fund founded in the University of Manchester for the provision of a memorial to the late H. G. J. Moseley (killed in action at Gallipoli, 1915), and originally proposed as a private memorial from Moseley's personal friends and fellow-workers in Manchester, has now been extended in order to give other scientific bodies, both in England and abroad, an opportunity of participating. This extension has been made at the request of a number of scientific men interested in Moseley's work, but not personally connected with him, and it is in order to reach this wider public that you are asked to publish this letter.

The scheme of memorial proposed is (1) the provision of a memorial tablet in the physical laboratory and (2) the foundation of a Moseley prize or medal for physics in the University of Manchester.

The fund is administered by a committee consisting of Sir Henry A. Miers (chairman), Profs. W. L. Bragg and H. B. Dixon, Sir E. Rutherford, and Dr. E. J. Evans.

Subscriptions, which should be made payable to the "Moseley Memorial Fund," and crossed "Williams Deacon's Bank, Ltd.," may be sent to either of the hon. secretaries, Mr. C. G. Darwin, Christ's College, Cambridge, or Dr. H. Robinson, Physical Laboratory, University of Manchester.

About 170*l*. has already been received, comprising donations from Great Britain, Canada, the United States, and France (including contributions from the Société Française de Physique and the Société de Chimie-Physique).

It is desired to close the fund in July of this year.

HENRY A. MIERS,
Chairman.
C. G. DARWIN,
H. ROBINSON,
Hon. Secretaries.

The Aurora of March 22–23.

I HAD a fine view of this superb display at Workington between midnight and 1 o'clock a.m., in a clear and bright starlit sky. The whole sky was filled with the light except a small area in the south-east. I could detect no colour except creamy-white, the general intensity being, to my mind, at times equal to full moonlight. Curtains of light surrounded a point just east of the zenith, which seemed to mark the "hub" of the display. The bright star (α) in Canes Venatici almost exactly marked this point, and filmy sheets of light seemed to dash upwards from the south-west and north-east horizons and merge together at this star. The only display I have ever seen to equal this was on 1907 February 14 at Motherwell, in the previous sun-spot maximum period. It was the fact that I could see the great sun-spot train on March 22 without telescopic aid that made me expect and look out for the aurora that night.

W. B. HOUSMAN.

Seaton Cottage, Workington, April 9.

The Nitrogen Problem: By-products.[1]

It is surely high time that we, as a nation, were more fully alive to the necessity of a complete investigation of the recovery of by-products, and that not merely in connection with nitrogen products. There is still too much of the feeling—one comes across it quite frequently—that so-called waste products form a recognised loss in any process. The investigation of the treatment of any waste product is not looked upon as the work of the person engaged in the specific manufacture from which that waste product is obtained. Competition becomes keener as the years pass, and if our position is to be retained by-products must be recovered in all cases where such recovery can be economically effected. A waste product may even become the starting point of a new industry. The detailed investigation of the position as regards nitrogen by-products manufacture comes as a very welcome record and as a much-needed indicator of the forward path.

The world's ammonia production, in terms of sulphate, advanced between the years 1903 and 1913 from 540,200 long tons to 1,389,790, an increase of more than 150 per cent. The chief producers were Germany, the United Kingdom, and the United States, who were respectively responsible in 1913 for 39, 31, and 12½ per cent. of the total production. The essential sources are gas-works, coke-ovens, gas-producers, shale-works, iron-works, and bone, etc., carbonising works.

In the years 1911 and 1913 the coke-oven industry was responsible for 84 and 86 per cent. respectively of the German production, in 1913 for 78 per cent. of the United States production, and in 1911 and 1913 for 27 and 30 per cent. of the United Kingdom production. The United Kingdom production rose from 233,664 long tons in 1903 to 432,618 in 1913, of which, in 1903, gas-works provided 149,489 long tons, or 64 per cent. of the total, which steadily increased to 182,180, or 42 per cent. of the total. Coke-ovens in the United Kingdom provided in 1903 only 17,438 tons, or barely 7½ per cent., but continual increase brought up the amount by 1913 to 133,816 tons, practically 31 per cent. of the production of the country. Iron-works during this period retained a steady output of 19,000 to 20,000 tons, shale-works production increased gradually from 37,353 to 63,061 tons, and that of producer-gas, bone, etc., carbonising works from 10,265 to 33,605 tons.

These are illuminating figures which deserve consideration and show plainly the development of the by-product industry up to the commencement of the war period.

In addition to supplying home demands for ammonia nitrogen, there was an average yearly export of ammonia, ammonia salts, and products made therefrom during the years 1911 to 1913 equivalent to 82 per cent. of the total home production. This would have been more than sufficient to provide the nitrate and nitric nitrogen required for all purposes had the means of conversion been available, which they were not, so that we were dependent on imported nitrates for various purposes, including agriculture, the manufacture of sulphuric acid, nitric acid, explosives, and other products.

Passing on to the war period, estimates for the year 1917 indicate a by-product ammonia increase of 130 per cent. in the United States, 27 per cent. in Germany, and only 6 per cent. in the United Kingdom; but Japan has in the meantime taken a considerable step forward and increased her output more than sixfold—from 8000 tons in 1913 to 50,000 tons in 1917. The production of sulphate from coke-ovens in the United States had increased by 1916 to 83 per cent. of the total output, and in the United Kingdom to more than 36 per cent. of the total. Even during 1915 and 1916 considerably more than half our production of ammonia nitrogen was exported, and we were using large quantities of imported nitrate, all of which might be produced economically by ammonia oxidation or by synthetic processes, details of which are fully discussed in the report. We have now arrived at the stage where synthetic manufacture begins to complicate the ammonia problem and the economics of the various processes require the closest attention.

With regard to post-war conditions, it is certain that agricultural demands will be much greater than formerly: many lessons were learnt during the war, not the least being that of the need for increased food production at home. The consumption of combined nitrogen practically doubled during the ten years preceding the war, and there is little doubt that the increase will continue, nitrogenous fertilisers being more and more in demand, especially now that much more land is under cultivation than in pre-war days; in fact, our own agricultural demand for fixed nitrogen in the form of sulphate of ammonia and nitrates was more than doubled during the war period only. Moreover, nitric nitrogen will be needed in increased quantities owing to the extension of chemical manufactures, such as dyes and drugs, which hitherto have been too much neglected; and with this will be involved the oxidation of by-product ammonia.

It would appear likely that the world's productive capacity should now be able to provide some 30 to 40 per cent. more combined nitrogen than in 1914, and this does not appear to be greater than would have been the case under normal conditions had the ordinary rate of growth in consumption in the pre-war period been maintained during the four years under consideration.

Now, if food production in this country is to

[1] "Ministry of Munitions of War. Munitions Inventions Department. Nitrogen Products Committee. Final Report." Pp. vi+357. (London: H.M. Stationery Office, 1919.) Cmd. 482. Price 4s. net. See also Nature, January 22 and 29.

be rendered independent of imported nitrogenous fertilisers, as is surely desirable—and recent conditions have shown that it may at any time become even absolutely necessary—and if this is to be coupled with a continued large export trade in nitrogen products, we must have a considerably increased production of ammonia nitrogen.

So far, practically all the by-product nitrogen has come from the manufacture of coal-gas, producer-gas, coke, and shale-oil; two possible sources have been practically untouched, viz. peat and sewage, though from the latter, owing to our position, perhaps little may be expected—certainly so unless some simple method should be discovered for recovering the soluble nitrogen from very dilute material. At the same time, it may be pointed out that the estimated annual amount of nitrogen in the sewage of the United Kingdom is 234,900 metric tons, 86 per cent. of which is in urine.

Power cost is, of course, the great factor in the question of by-product recovery *versus* synthetic manufacture, and this is affected by coal cost: the problem is fully discussed in the report. But questions of the first importance to the by-products industries, which must strive to increase production, are such questions as the efficiency of work on existing processes, the modification and further development of such processes, and the introduction of new methods.

Reviewing the gas industry, it is seen that, with existing methods, an increase in the amount of sulphate of ammonia recovered should certainly be expected. Many small gas-works run to waste the ammonia liquor, chiefly owing to their isolated position; a proposal is made in the report to work up liquors at small works in travelling sulphate plants, but this has been attempted in several instances and afterwards abandoned. One would remark, however, that some small works might well adopt the direct system of recovery, which has in some cases served very well, and a local demand for the sulphate produced would obviate cost of transport. A general consideration of the direct method of recovery demands more attention than has been given to it; much has been done and published in recent years by the Chief Alkali Inspector. Storage of ammoniacal liquor still needs attention; there are in use inefficient methods of running ammoniacal liquor into imperfectly covered wells and tanks: this point is strongly indicated in the report. In dealing with concentrated ammonia liquor, the losses are apt to be particularly heavy. It is considered that several thousand tons of sulphate might be added yearly to the gas industry ammonia recovery by attention to such matters as these. Moreover, it will be necessary to produce a somewhat higher grade and at the same time a neutral sulphate. But a question that demands perhaps even more attention is the introduction of new methods whereby the sulphur content of the gas itself would be made available, and so transport and use of sulphuric acid avoided. The Burkheiser and Feld processes still require to be worked out satisfactorily, and quite recently comes the proposal of Cobb to use sulphate of zinc as a starting material. These methods are perhaps all the more worthy of careful investigation owing to modern developments in the manufacture of coal-gas; the increase in the vertical retort method of carbonisation, coupled with steaming, has given rise to increased quantities of liquor of decreased strength.

In the metallurgical coke industry many of the bee-hive plants have disappeared in recent years, and this has, of course, had its effect on the ammonia production. There is now no longer any question as to the relative merits of bee-hive and by-product oven coke, and proper treatment might lead to an increase of 10 per cent. or more on the present total production of ammonia from all sources.

In the producer-gas industry, again, there is scope for investigation; scarcely sufficient stress appears to be laid on producer-gas practice as regards steaming and liming. Hydrated lime certainly has a quite appreciable effect on ammonia production, and it would seem, moreover, to admit of greater latitude in the choice of the coal used.

It is unfortunate that peat has not received more attention in this country; apart from nitrogenous by-products, some of the by-products from peat gasification appear to have quite a special value, judging from results obtained in Scotland and Ireland. Moisture and transport are, however, difficulties, yet schemes for the utilisation of peat on the spot might well be considered from a power point of view, even though the addition to the by-product nitrogen production would not be by any means of the first order.

A Survey of National Physique.[1]

ONE of the more valuable after-results of the great wars in the last century was the increased interest aroused in regard to national physique, leading to various measures directed towards its improvement. After the Napoleonic wars there arose the great gymnastic clubs of Central Europe and Scandinavia, which laid the foundations of physical education on a wide scale. The Civil War in America led to the first great demographic survey, the data of which were rendered public in the report of the Surgeon-General of the Federal armies on the statistics of the recruiting bureaux. The War of 1870 was followed by surveys of the population in Germany, and on a smaller scale in France, which to a large extent

[1] Ministry of National Service 1917 19. Report, vol. i., upon the Physical Examination of Men of Military Age by National Service Medical Boards from November 1, 1917-October 31, 1918. Pp. iv+159+charts. (London: H.M. Stationery Office, 1920) Price 6s. net.

formed the basis of our ethnographic knowledge until the present time. The South African War led to the Commission on Physical Deterioration in England and Wales, and to a similar Commission on Physical Education in Scotland, from the labours of which resulted the introduction of medical inspection and treatment of school children, and perhaps in part also the National Health Insurance Act.

The Report of the Ministry of National Service on the Physical Examination of Men of Military Age by National Service Boards contains a survey which in extent, in wealth of demographic detail, and in narration of the associations of inferiority of physique surpasses all previous efforts in this country, and is approached elsewhere, as yet, only by the report of the American Surgeon-General's Department mentioned above. If similar data could have been collected from all examinations from the commencement of the war, a practically complete survey would have been available for the use of future social hygienists. It is probable that the earlier figures are irrecoverable, which may mean that while we shall in the future be equipped with a knowledge of the nature and sources of physical failure, we shall have fewer data as to the measure of physical fitness among the better-endowed members of the community. The anthropologist will thus derive rather less from the report than the social economist and hygienist.

The first volume of the report, which is all that is, as yet, issued, contains a brief introduction; sections on grading as a criterion of health, the comparison of grading results, the relation of occupation and health, the causes of low grading and rejection; and regional reports from the district Commissioners. Under each head there is a series of statistics chiefly taken from special areas, but an analysis of all available observations on physique and disabilities is promised for the second volume, which is stated to be in active preparation, and will present a complete survey of the conditions in Great Britain. The data available are taken from nearly two and a half million examinations, on a carefully standardised uniform system, the subjects being classified into four grades. Owing to re-examinations, the actual numbers of individuals would be slightly smaller save in the case of those rejected as totally unfit for service.

Grade 1 consists of those who attain to the full normal standard of health and strength, and are capable of enduring physical exertion suitable to their age. They have no progressive organic disease or serious disability or deformity. These constituted 36 per cent. of the total.

Grade 2.—Those who fall short of Grade 1 by reason of partial disabilities amounted to between 22 and 23 per cent.

Grade 3.—Those who presented such marked physical disabilities or such evidence of past disease as to be deemed unfit to undergo the degree of physical exertion required for the former, but including those fit only for clerical or sedentary work, amounted to 31–32 per cent.

Grade 4.—Those permanently and totally unfit for any form of military service numbered 10 per cent.

The proportions found in the different grades varied from time to time and from place to place according to whether the numbers coming up for examination consisted largely of older categories and those who had been rejected previously, or of those just attaining military age and those just combed out from previously protected occupations. In the main the distribution is in accordance with probabilities, with the average, however, not, as might have been hoped, among the fit, but among those with partial disabilities.

Prof. Keith submitted a comment on the earlier reports of the boards showing that on the basis of the average man being fit 70 per cent. ought to be in Grade 1, 20 per cent. in Grade 2, 7½ per cent. in Grade 3, and 2½ per cent. in Grade 4. In practice there is a grave deficit from this, though the results of examinations of certain groups, as of miners from the western part of the Welsh coalfield and of miners and agriculturists from Yorkshire during the period of the combing, showed that this theoretical standard was attained by the best of the community. Bearing in mind the physique of many who went to military service in the earlier years, and of many who remained to the end in protected occupations, the total deficit of the country is probably less than would appear from the figures in this report, yet enough is shown to indicate the need for ameliorative measures.

Prof. Keith points out that from every area, or at least from numerous and representative sample districts, there should be not only the full return of grading, but also frequency tables of stature, weight, and chest dimensions, so that anomalies in grading may be manifest and the nature of the deterioration in physique detected. He suggests that indices of fitness should be determined and shown on maps, which could then be compared with maps of other physical and social data. The indices he suggests are an index of efficient fitness or the percentage of Grade 1 men, and an index of average fitness to be derived by assigning 1 unit to each Grade 1 man, ¾ unit to each Grade 2, ½ unit to each Grade 3, and ¼ unit to each Grade 4, the whole being then added and expressed as a percentage of the total number of men examined. Many such data are given for isolated areas, so it is to be hoped that the maps may appear in vol. ii., when they will carry more conviction than tables or diagrams. Graphs of the frequency of the different gradings are given month by month for the areas, with, in the regional reports, some commentary on the classes examined. The total results show a relative inferiority in the southern part of the country.

The measurements recorded in this volume show an average for Grade 1 of 5 ft. 6 in. stature, 130 lb. weight, and 34 in. chest girth. The

general averages vary from area to area, but show, on the whole, a close similarity to those obtained by Roberts and by the Anthropometric Committee for the artisan classes some forty years back, though in this volume there are not enough data to enable the different areas to be contrasted on an ethnographic basis.

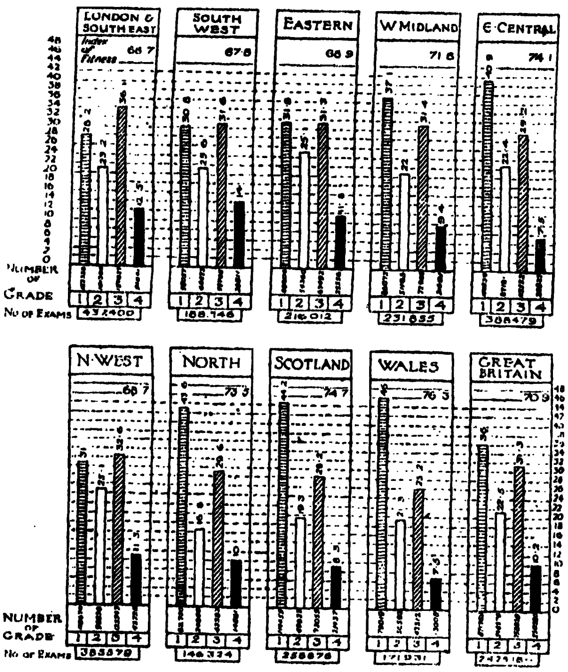

FIG. 1.—Graphical representation of physical fitness in each region of Great Britain. The diagrams show for each region the actual numbers and percentage for each grade, as well as the index of fitness. They provide, therefore, a convenient means of comparing the relative physical condition of the respective populations.

Physique and general fitness fall off with advancing years, and it is noted from several areas that after the age of fifty practically no recruits of military value are to be obtained. One Commissioner generalises the observations by pointing out that while the physical standard of early manhood was determined by inheritance modified by environment, above the age of forty, the determining factor was how a man had lived his earlier life.

The variation in physique with different occupations is very marked, as can be seen from the respective indices of fitness of groups, though it would perhaps be well to defer detailed comparison until full figures are available. The following may serve as illustrations:-

Occupation	Index of fitness	Per cent. in Grade
Munition workers and colliers, St. Helens	92·8	81·8
Colliers, Wigan	91·7	77·4
Colliers, West Wales ...	90·5	76·0
Agriculturists, Yorks	89·9	74·8
Engineers, Yorks	85·9	60·9
Iron and steel workers ...	85·7	60·2
Lace workers	77·4	45·0
Woollen trade	75·7	37·5
Tailors	69·5	33·0
Cotton operatives, Stockport	57·9	19·6

This is also seen by comparison of towns—*e.g.* in March, 1918, Sheffield showed an index of 83·3 with 61 per cent. in Grade 1, and Leeds an index of 62 with 14·5 per cent. in Grade 1. It is evident that the men of good physique are found in the heavier occupations. Among the causes of low grading, heart disease and tuberculosis take a high place, while in some areas there is a prevalence of infantile paralysis. Contrary to expectations raised by the recent campaign on public morals, the incidence of venereal disease as a cause of low grading is nearly negligible. A special series of charts shows the full data obtained as to the relation between occupation grading and disease in the London area. Sedentary occupations show the worst results, and it is a question whether in part it is not as much that those of inferior physique gravitate to sedentary work as that this in itself is harmful. Heart and circulatory disease, and to a less extent congenital or acquired deformities, constitute the chief causes of deficiency.

The information available in this volume is such as to require almost a separate description for each section, and the Ministry is to be congratulated on a volume which should be on the shelves of every social worker and reformer.

The Doctor of Philosophy in England.

THE neglect on the part of the English universities in not recognising a special faculty of philosophy has been remarkable, but this singular circumstance is of rare interest to the student of the history of universities. It is a curious fact indeed that the title of doctor itself dates, though with some uncertainty, to the first half of the twelfth century at Bologna, and to the middle of that century at Paris. About a century later the doctorate in law and divinity came into use in England, and in the fourteenth century followed that of medicine. In the fifteenth the English universities took the lead in conferring the degree of doctor of music. Yet doctorates in grammar, logic, and philosophy were given in Germany so early as the thirteenth century. Until comparatively recently the M.A. in England ranked above the Mus.Doc.

To those acquainted with the history and the evolution of degrees, that of master of arts must carry the greatest respect, if not veneration, from the point of view of antiquity, for it conveys with it the first traditions of the spread of learning in Europe, being as it is by far the oldest of degrees. The earliest teachers bore the titles of lord, master, and judge (*dominus, magister, judex*), which were in common use long before that of doctor. In fact, to this day the German

Ph.D. is primarily a master of arts, the degree being properly *Magister Artium et Doctor Philosophiae,* and is given for research, just as the Cambridge research M.A. is to-day. Whether the Cambridge research student who has already taken his M.A. will be qualified before long to add Ph.D. to his name remains, however, to be seen. Rashdall, in his "Europe in the Middle Ages," ridicules the practice now becoming prevalent in England of giving the master's and doctor's degrees in the same faculty; as, for instance, the LL.M. and LL.D. at Cambridge. Just as a doctor may have been learned in his own faculty, so was the master supposed to be supreme in his. In fact, the terms master, professor, and doctor were in the Middle Ages almost identical; and until Cambridge introduced the anachronism of the LL.M. in the nineteenth century, the master had always been regarded as equivalent to the doctor in his own special faculty. But the fusion of the two in Germany in the Ph.D. was in strict accordance with tradition, and perfectly correct.

It may be recalled that in England in the Middle Ages, as in Paris, teachers of law were styled doctors, and those of theology masters. The doctor of divinity, on the other hand, was a characteristic of Bologna, and the jealousy existing between the universities tended for some time to keep these features distinct.

In recent times, however, the doctorate has assumed a higher rank than the masterate. The University of Yale in 1860 first conferred the degree of Ph.D. after the German style, and this was followed by other universities in the United States. The commercial aspect of the question being of importance, there has been a strong tendency in recent years to recognise the disadvantages imposed upon students of research in this country, as compared with their rivals from Germany and the United States. For some time past—in fact, since 1895—Cambridge has given a Certificate for Research with the B.A. and M.A.—a distinction which is understood to rank with a first class in Part II. of the Tripos. This certificate testifies the candidate's dissertation to be "a work of importance and distinction as a record of original research." It is about the same standard as the German Ph.D. But the general public, being little acquainted with these innovations, continued to regard the Ph.D. as the hall-mark of respectability for all research workers, even in this country.

During the last year or two, however, Oxford, perceiving the need, has instituted the degree of D.Phil. for the benefit of those (*a*) who have attained the status of advanced student in the university, by having been placed in the first or second class in the Final Honours School, or in the first class in an Honours School of the First Public Examination, and passed all necessary examinations for the degree of B.A.; (*b*) students from other universities who have attained a similar standard, and can produce evidence of fitness to engage in research, having pursued a course of study at one or more universities extending over four years at least. After two years at Oxford, such students may, as a rule, apply for the D.Phil. by presenting a dissertation, which must constitute an original contribution to knowledge, set forth in such a manner as to be fit for publication *in extenso*, being, in the opinion of the examiners, of sufficient merit to qualify for the degree.

The example of Oxford has been followed by Cambridge. A new statute authorising the degree of doctor of philosophy for research has been approved by the Privy Council, and the regulations will be put before the Senate at the first Congregation in the Easter term. The statute will rescind the old regulations relating to research students. As in the case of Oxford, the status of an advanced student, known now at Cambridge as research student, must be attained, whether by graduates of Cambridge or by students from other universities. (*a*) A student, being a graduate of Cambridge, who has from the time of his admission as a research student pursued in the university, or in some other recognised place of study, a course of research for not less than three years, one year of which has been spent at Cambridge, and two either at Cambridge or at some other recognised place of study, may, not earlier than the ninth, and not later than the twelfth, term from his admission as a research student, submit a dissertation embodying the results of his research. (*b*) A student who, not being a graduate of the university, has kept by residence not less than six terms in a course of research, and pursued research for not less than three years, two of which have been at Cambridge, and one either at Cambridge or elsewhere recognised by the authorities, may, not earlier than his ninth, and not later than his twelfth, term as a research student, submit a dissertation embodying the results of his research. It is not quite clear whether, and if so what, provisions are made for those research students who have already taken the research M.A. having worked for the prescribed period at Cambridge or elsewhere.

At present a master of arts of five years' standing—that is, *twelve* years from matriculation—may apply for the Sc.D. The fee varies from twenty-five guineas to nearly 50*l*., according to the college. But very few ever proceed to this, since by the time the necessary status is reached most men consider that they have had sufficient patronage and paid enough for their education to trouble about it. They are usually by that time tired of examinations and of submitting themselves to the criticism of examiners, some of whom, having remained at the university, holding small teaching appointments, may not have attained quite the same status in the outer world.

It is a matter of importance that examiners for such degrees should have the confidence of the candidates, as well as of the university authorities, as being at least their equals, if not superiors,

in the knowledge of the special subjects of the dissertations; for at some universities professors who have never published anything whatever are asked, as professors, to examine, for the doctorate, candidates with a European reputation! An instance of this nature has recently occurred in one of the universities in this country, the professors being almost unknown outside its walls. But no doubt Oxford and Cambridge may be trusted to stand above rendering such an injustice to those who seek their recognition and come from afar for the benefits they bestow.

British Crop Production.[1]

By DR. EDWARD J. RUSSELL, F.R.S.

FODDER and hay crops play a more important part than cereals in the economy of the farm, because they are the raw materials for a highly important part of the farmer's business—the production of meat, milk, or butter. They are too bulky to transport in any quantity, and farmers use only as much as they themselves grow. The output of meat and dairy produce is, therefore, limited by the quantities of these crops at the farmer's disposal. The quantities produced just before the war and in 1918 were:—

Production of Fodder and Hay Crops.

	Yield per acre 1908–17		Acreage. Millions of acres				Total produce. Millions of tons	
	England and Wales	United Kingdom	England and Wales		United Kingdom			
	tons	tons	1914	1918	1914	1918	1914	1918
Swedes	13·0	14·6	1·04	0·91	1·75	1·60	24·2	22·8
Mangolds ...	19·5	19·5	0·43	0·41	0·51	0·50	9·5	10·3
	cwt.	cwt.						
Hay (temporary)	29·1	32·2	1·55	1·45	2·90	2·80	4·2	4·4
Permanent grass	22·6	27·9	4·79	4·30	6·49	5·95	8·2	7·9

Like cereals and potatoes, these crops are greatly affected by artificial fertilisers, especially by phosphates, which increase not only the yield, but also the feeding value per ton. This is strikingly shown in the case of swedes and turnips, which receive a large part of the superphosphate made in this country. Mangolds respond remarkably well to potassic fertilisers and to salt. There is much to be learned from a systematic study of the influence of artificial manures on the composition and feeding value of these crops under the varied conditions of this country.

A further reason for the important part played by these crops in the economy of the farm is that they profoundly affect the fertility of the soil. They do not remove from the soil all the fertilising constituents which must be added to secure maximum growth; some of these constituents are left behind in the soil to benefit the next crop—a rare instance of double effectiveness for which the farmer ought to be profoundly thankful. In the second place, even the fertilising constituents which are absorbed by the crop are not entirely retained by the animal; considerable quantities are excreted and pass into the manure, and again are added to the soil. There is, therefore, the possibility of constant improvement of the soil; larger fodder crops enable more livestock to be kept, more livestock make more manure, and more manure gives still larger crops. It is sometimes argued that meat or milk production is in some way opposed to corn production, but on this method there is no antagonism; on the contrary, each helps the other. The production of more meat is consistent with, and indeed involves, the production of more corn.

The simplest way of utilising animal excretions without loss is to allow the animals to consume the crop on the land where it grows, and this is frequently done excepting where the soil is so sticky as to become very unpleasant in wet weather. Sheep are the best animals for the purpose, as they are easily penned in by light hurdles, these being moved as each portion of the field is cleared; this folding is a common occurrence on the chalky and sandy soils of the Southern and Eastern Counties.

Bullocks are less tractable, and cannot be enclosed by light hurdles; they are, therefore, generally kept in yards, roofed in if possible, but oftentimes open. Sufficient straw is added to provide them with bedding and to soak up the excretions. In this way the fertilising constituents of the straw as well as of the food are returned to the soil.

In the case of dairy cows the treatment is rather different; they have to be housed properly in quarters which are sometimes palatial, and for hygienic reasons they are allowed but little bedding. Their manure is removed once daily—sometimes oftener—the primary object being to get it away without contaminating the milk. The investigations already referred to for which Lord Elveden provides the funds are now being extended to the dairy farm to see how far it is possible to save the manure without prejudice to the purity of the milk.

In the old days, when farmyard manure was the only manure and the old type of implements alone were available, farmers had to arrange their crops on a definite plan in order to get through their work and maintain permanently the productiveness of the land. There thus grew up a system known as the rotation of crops, which contributed very largely to the agricultural developments of the 'sixties, and ultimately became a rigid rule of husbandry strictly enforced over large parts of the country. Modern cultivation implements and fertilisers justify much more latitude, however, and no good farmer ought to be restricted in his cropping, provided, of course, that he maintains the fertility of his land. It is sometimes a convenience on the dairy farm to grow the same crop year after year on the same land, and the Rothamsted experiments show that this can be done, excepting only in the case of clover. With this exception there is no more need to have a rotation of crops than there is to have a rotation of tenants in a house. It is essential, however, that the land should be kept free from other competitors and from disease germs. Freedom from competition means the exclusion of weeds. In the old days this had to be effected by periodical bare fallows. Nowadays a different course is possible; modern cultivation implements worked by a tractor allow great scope for the suppression of weeds. There is, however, one crop that must be grown periodically to ensure the best results—clover or a mixture of clover and grass. Clover affords valuable food for cattle during winter, and it also enriches the soil in highly valuable nitrogenous organic matter. Much of this is the work of the plant itself, and could equally well be done by grass; but the enrichment in nitrogen is the work of bacteria residing

[1] Discourse delivered at the Royal Institution on Friday, February 20. Continued from p. 178.

in the nodules in the clover-roots, and is unique among the phenomena of the farm.

Unfortunately, clover, unlike other crops, cannot be grown frequently on the same land, and, consequently, the farmer is unable to make as much use of it as he would like. Investigators have for many years been trying to increase the effectiveness of the clover organism, but without result. Inoculation of the soil with virulent strains has been tried, but it was unsuccessful in this country, although results are claimed in the United States. The problem has recently been taken up at Rothamsted, and one reason found for the previous failure. The organism has several stages in its life-history, one of which is a period of rest; some conditions favour a long rest, others a shorter one, and Mr. H. G. Thornton is endeavouring to find out how to increase the activity of the organism in the soil and ensure that its work shall be done. Attention is being devoted also to the causes of failure of the crop. The clover crop furnishes some of the most important problems in arable farming before us.

In the meantime, a working solution lies in growing an admixture of grasses with the clover. This reduces the risk of failure while considerably benefiting both soil and farmer.

A typical arable district is thus a busy region in which both farmers and workers are kept constantly occupied. The crops claim attention all through the year, and particularly in summer, while in winter the animals need attention. Four or more men can be regularly employed per 100 acres. An organised village life has developed, having distinctive characteristics of its own and presenting endless scope for the intelligent social worker.

Grass farming, on the other hand, stands out in sharp contrast with all this. The grass farmer puts his animals into the fields, and Nature does the rest; when they are fat he sells them to the butcher. It is essentially summer work; the winters are left free. As no man can long remain idle, there has been an extensive development of hunting and its attendant occupation, horse-breeding, in the English grass regions. While the grass farmer's life is not idyllic joy, it is, at any rate, free from much of the worry and uncertainty of arable farming, and it brings in sufficient money to ensure a modest competence. One can quite understand the reluctance of the farmer to quit this path of safety.

If one could accept the doctrine that a man could do what he liked with his land, the grass farmer could be left alone and reckoned among Virgil's too happy husbandmen. But this doctrine is now somewhat out of court, and the needs of the community have also to be taken into account. From this point of view grass husbandry, in spite of its safeness for the individual farmer, is not so good for the community as arable farming, since it is less productive per acre of ground. This was realised before the war, and was vividly brought to the notice of farmers by Sir Thomas Middleton, who drew up the following table:—

Number of Persons who could be Supplied with Energy for One Year from the Products of 100 Acres of

Poor pasture converted into meat	...	2–4
Medium pasture ditto	...	12–14
Rich pasture ditto	...	25–50
Arable land producing corn and meat		100–110

The area of rich pasture is very restricted. An improvement can often be made in poor and medium pasture by the use of basic slag, by drainage, and in other ways, but the results could probably never surpass those now obtained on rich pasture. None of them approach the results obtained on arable land.

During the war, therefore, the policy of the Food Production Department was to convert grassland into arable, and much was done; but now that the element of compulsion has disappeared some of the arable is going back to grass. It is not that the farmer is trying to avoid work; he is impressed by the greater risk of arable farming,[2] and, above all, he desires to keep to the well-established principle that his system of husbandry must suit the local conditions. This is strikingly shown by the following returns from a large number of farms:—

Collected by the Agricultural Costings Committee.

	Income per			Expenditure			Profit[3] per acre			Capital per		
England and Wales—	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.
Mixed farms ...	9	12	5	10	2	11	1	7	2	13	9	0
Dairy farms ...	14	17	0	13	18	5	1	7	4	15	7	0
Corn and sheep	7	7	1	7	4	10	1	14	2	12	16	9
Large sheep farm	1	4	3	0	17	6	0	8	5	1	7	10
All Scottish ...	5	10	9	4	15	10	1	4	11	7	7	9

The profit per acre from the large sheep farm is small in itself, but it is large in proportion to the capital and the expenditure, and, given a sufficient acreage, the farm is more lucrative than the more risky mixed or dairy farms. The risk of corn production can, and probably will, have to be met by some system of insurance or guarantee; but the need to conform to local conditions will always remain.

The problem therefore arises: Can a system of husbandry be devised which suits the natural conditions as well as grass, and is as productive of total wealth as arable crops? I believe this can be done. Grass is not the only crop adapted to moist conditions or heavy soils, and appropriate for the production of meat and milk. Many other leaf or root crops serve as well, some of which yield much more food per acre than does grass. Vetches, rape, mangolds, kale, and marrow-stem kale can all be used direct, and there are various mixtures of oats with peas, tares, vetches, etc., that can be fed green and made into hay or silage as the farmer may wish. The use of these crops in the place of grass for the feeding of livestock is known as the soiling system.

We are only just beginning to discover the combinations of crops best suited to particular conditions. An interesting experiment is in progress at the Harper Adams Agricultural College, which, however, should be repeated elsewhere. Each crop is governed by the same general laws as hold for cereals. In each case the yield and feeding value can both be increased by the proper use of artificial fertilisers, and there is the further possibility of great improvement by the plant-breeder.

It is in this direction that I think British agriculture will develop in the future. The system is strictly in accordance with the laws of science, and therefore it needs a minimum amount of artificial support. It gives the farmer abundant scope for the production of livestock, which he has always regarded as his sheet anchor, and the community an abundant production of food per acre. Most important of all, while

[2] On our ordinary farm at Rothamsted (distinct from the experimental land) the expenditure on arable land is continuously increasing, while that on the grassland is much less. The figures are :--

	1913-14			1917-18			1918-19	
	£	s.		£	s.		£	s.
Wheat	5	7	...	10	14	...	14	0
Oats	6	4	...	9	7	...	14	5
Roots	17	10	...	20	18	...	16	0
Potatoes	21	1	...	37	11	...	46	0
ay)	3	12	...	4	16	...	6	0
			...	2	4	...	3	0

Direct wage payments account for about 40 per cent. of the expenditu arable land, but for less than 15 per cent. of that on grassland.

[3] Including change in valuation.

retaining the best features of our present arable and grass systems, it allows of considerable further development.

I shall not venture any opinion as to how far we could go in feeding ourselves. The accompanying table shows what we did before the war, and what, on our present technical knowledge, we could do now, assuming that the insurance problem of covering the extra risks of arable farming were solved, and assuming also a reasonable increase in the efficiency of labour.

In this country we can certainly hope to find the solution of the insurance problem, and I hope and believe of the labour problem also. Our output per acre of the arable crops is distinctly above that of many other countries, though we no longer lead as we did in the 'sixties. Our output per man, however, is not particularly good, and is open to considerable improvement. Those who know the agricultural labourer best have the fullest faith that his sterling qualities will enable him to rise to the new levels of industrial capacity which the man of science and the engineer have opened out for British agriculture. There are anxious days ahead, but with wise and sympathetic treatment the difficulties can be solved and our future assured.

Consumption and Production of Human Food in the United Kingdom. Million Tons per Annum.

	Consumption (1909–13)	Home production: Pre-war	Home production: 1919[4]	Home production: Estimated attainable
Wheat, barley, and oats	13·4	6·5	7·0	10·0
Other cereals*	3·5	—	—	—
Potatoes	5·5	4·8	6·3	7·0
Dairy produce	5·2	4·7		5·0
Meat	3·0	1·8		2·5

[4] Mr. McCurdy gives the following details for 1919 (see *Times*, February 18, 1920):—

Consumption and Production of Food in the United Kingdom, 1919.

Commodity	Estimated total consumption Tons	Proportion of home-grown and imported produce included: Home-grown Per cent.	Imported Per cent.
Wheat	7,395,000	27	73
Barley	1,950,000	64	36
Oats	4,297,000	92	8
Beef and veal ...	995,000	66	34
Mutton and lamb ...	368,000	57	43
Bacon and hams ...	447,000	19	81
Butter	180,000	58	42
Cheese	145,000	30	70

Notes.—Cereals: The quantities are given after deduction for seed, and in the cases of wheat for tailings also. Bacon: The quantities given are for bacon as smoked or dried.

Obituary.

THE death of M. LUCIEN POINCARÉ, Vice-Rector of the University of Paris, on March 9, at fifty-eight years of age, will be felt as a great loss, not only to higher education in France, but also to the *entente* between the universities of that country and those of Great Britain. Only a fortnight before M. Poincaré came to England, accompanied by Mme. Poincaré, to open the British branch of the Office National des Universités et Ecoles françaises, housed with our own Universities of the Empire Bureau in Russell Square. His speeches on February 23, at the Bureau, and on February 24, at the University of London, where he was given a special reception, and at the Lyceum Club, left on his hearers a deep impression of charm, of width of knowledge, of sound judgment, and of sympathy. M. Lucien Poincaré, like his brother Raymond, former President of the French Republic, and his cousin Henri, the great mathematician, came from Lorraine. He was a physicist by training, and took his doctor's degree with a thesis on the resistance of fused electrolytes. Like most French physicists, he began his teaching career in secondary education, and was a master first at the Lycée of Marseilles, and then at the Lycée Louis-le-Grand in Paris. For a time he was *chargé-de-cours* at the Paris Faculty of Sciences; later he entered on an administrative career and held successively the posts of Rector of the Académie of Chambéry, of Inspector-General and then Director of Secondary Education, and of Director of Higher Education at the Ministry of Public Instruction. In October, 1917, M. Poincaré was appointed official head of the University of Paris (the most distinguished post in French university administration) in succession to the veteran M. Liard.

THE death is announced, at sixty-four years of age, of PROF. HECTOR TREUB, the eminent professor of gynæcology in the University of Amsterdam.

THE death of MR. H. S. B. BRINDLEY is recorded in *Engineering* for April 9 as having occurred on March 28, only three days before his name appeared on the list of newly created Knights Commanders of the British Empire. Mr. Brindley was born in 1867, and educated at the Tokio Engineering College, where his father was an instructor. He had wide experience with several engineering firms, and will be remembered chiefly by his energetic development during the war of a disused artificial stone factory at Ponders End into a shell and gun factory employing more than five thousand hands, a task which could have been accomplished only by a very exceptional man.

BY the death, lately announced, of MR. W. J. RAINBOW, the Australian Museum of Sydney, New South Wales, has lost the services of an entomologist who for twenty-four years laboured with assiduity and success to make the collection of insects and Arachnida in that institution worthy of a great colony, and has thereby laid all students of those classes under a lasting obligation. Mr. Rainbow's published works include treatises on certain groups of Lepidoptera and Diptera; but his main attention was given to the study, and especially the life-history, of spiders and scorpions. His papers on Arachnida are sixty-seven in number, one of the latest being devoted to a description and classification of the Araneidæ brought from Macquarie Island by the expedition under Sir Douglas Mawson.

Notes.

PROF. C. J. MARTIN, F.R.S., director of the Lister Institute of Preventive Medicine; Sir William Orpen, K.B.E.; and Sir J. E. Petavel, K.B.E., F.R.S., director of the National Physical Laboratory, have been elected members of the Athenæum Club under the provisions of the rule of the club which empowers the annual election by the committee of a certain number of persons "of distinguished eminence in science, literature, the arts, or for public service."

THE Royal Danish Society of Science has elected Sir Ernest Rutherford and Sir Joseph Thomson as fellows in the physical and mathematical class, and Sir George Grierson and Prof. W. M. Lindsay fellows in the historical and philosophical class.

DR. A. MCWILLIAM, formerly assistant professor of metallurgy in the University of Sheffield, and now a consultant metallurgist in that city, was invested by the King with the Order of C.B.E. on March 20. This honour was conferred upon him for his general war work in India, principally in connection with the supply of steel for war purposes.

As already announced, the Geological Survey and the Museum of Practical Geology were transferred from the Board of Education to the Department of Scientific and Industrial Research on November 1 last. The Lord President has now appointed a Geological Survey Board for the management of the work of the Survey and museum, and to submit from time to time recommendations on developments that appear to be necessary as the work progresses. The Board, as at present constituted, consists of Sir Francis G. Ogilvie (chairman), Prof. W. S. Boulton, Prof. J. W. Gregory, Dr. John Horne, Prof. J. E. Marr, Mr. Frank Merricks, and Mr. W. Russell.

SIR HENRY HOWORTH has presented to the Geological Department of the British Museum (Natural History) the collection of mammalian and other remains obtained by Mr. W. J. Lewis Abbott from a fissure near Ightham, Kent. This collection is especially important on account of the care with which the bones of the small animals were extricated and preserved. The ordinary larger specimens belong to the woolly rhinoceros, mammoth, reindeer, stag, roebuck, horse, and hyena, and show that the greater part of the fauna at least dates back to the latter part of the Pleistocene period. All the circumstances of the discovery were discussed by Messrs. Abbott and E. T. Newton in the Geological Society's Quarterly Journal in 1894.

DR. CARLOS AMEGHINO, director of the Argentine National Museum, announces that he has recently discovered the oldest known remains of man at Miramar, near Mar del Plata, on the coast of the province of Buenos Aires. Human remains were found in the same district several years ago in association with stone implements and with bones of the extinct Toxodon and ground-sloths; but according to the observations of Dr. Aleš Hrdlička and Dr. Bailey Willis (Smithsonian Institution, Bureau of American Ethnology, Bulletin 52, 1912), they are of no great antiquity, and probably represent a modern South American race. All the supposed discoveries of early man in America have hitherto proved unsatisfactory, and Dr. Ameghino's detailed report on the latest find will be awaited with interest.

CAPT. VAUGHAN-WILLIAMS, who is excavating the supposed site of Edward the Confessor's palace in Windsor Great Park, has discovered what is believed to be the dedication-stone of a Saxon place of worship. Upon the stone are the marks of a cross and what looks like Saxon lettering. Among other discoveries are the remains of a kitchen and banqueting-hall and the traces of what seem to be Roman baths. This confirms the statement of Mr. Forestier that the palace of the Saxon king was built upon the site of a Roman villa, which was provided, as usual, with a series of baths. The remains of the chapel indicate that it was 40 ft. long, and, according to Bishop Browne, who recently inspected it, it contained an altar for the worship of God, and one smaller for the worship of devils.

NINETEEN years ago the splendid survivor of the Great Trilithon at Stonehenge was in a very dangerous condition, but it was set upright again, and now the Office of Works, in association with the Society of Antiquaries, is engaged in restoring to a position of safety other stones that are in danger. A question of interest has been raised during the work now in progress. Just inside the Ditch a circle of holes has been discovered in the chalk, which mark the site of an outer circle of stones. In these holes have been found charred human bones, bits of burnt animals' bones, or only a single tine of a stag's horn. Aubrey's map, made in 1666, showed in approximately the position of these newly found holes a series of depressions in the turf which have since then disappeared. In one was shown a stone which has since been removed. The detached stone, well known as the "Slaughtering Stone," which lies in line with the "Hele Stone," appears to fit almost exactly into place in this new circle. Whether it is the last survivor of an outer circle of stones, and whether this outer ring was coeval with Avebury and made before Stonehenge itself existed—these are questions which cannot now be answered until further excavations help to solve the problem.

THE James Forrest lecture for the present year will be delivered at the Institution of Civil Engineers by Sir Dugald Clerk at 5.30 on Tuesday, April 20. The subject will be "Fuel Conservation in the United Kingdom."

THE fourth Guthrie lecture of the Physical Society of London will be delivered on Friday, April 23, at 5 o'clock, by M. C. E. Guillaume, who will take as his subject "The Anomaly of the Nickel-Iron Alloys: Its Causes and its Applications."

SIR GEORGE NEWMAN will deliver the Lady Priestley memorial lecture of the National Health Society on Thursday, April 22, at the Royal Society of Medicine.

His subject will be "Preventive Medicine: The Importance of an Educated Public Opinion."

The Wilbur Wright lecture of the Royal Aeronautical Society for the present year will be delivered on Tuesday, June 22, at the Central Hall, Westminster, by Comdr. J. C. Hunsaker, U.S.N., who will take as his subject "Naval Architecture in Aeronautics."

Under the auspices of the National Union of Scientific Workers a public meeting, presided over by Mr. H. G. Wells, is to be held at 8 o'clock on Wednesday, April 28, in the lecture-theatre of Birkbeck College, Breams Buildings, E.C.4, addressed by Prof. F. Soddy on "The Public Support of Scientific Research." The address will be followed by a discussion.

The Scottish Shale Oil Scientific and Industrial Research Association has been approved by the Department of Scientific and Industrial Research as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. The association may be approached through Mr. W. Fraser, C.B.E., Scottish Oils, Ltd., 135 Buchanan Street, Glasgow.

A communication has been received from the Decimal Association criticising the recent report of the Royal Commission on Decimal Coinage. The association maintains that the report cannot be accepted as final for the following reasons, among others:—The Commission ignores the fact that eleven of our Colonies or Dependencies have already adopted decimal coinage, and that our non-decimal Dominions have repeatedly advocated the establishment of the decimal principle in currency. Further, the report exaggerates the difficulties which would be caused by the abolition of the penny, and takes no account of the altered and daily decreasing purchasing power of that coin. The Decimal Association considers that the first minority report represents the actual opinion of the community, and that the decision given in the main report is short-sighted and unpopular. For these reasons the association intends to persist with its active propaganda in favour of the reform.

In *Ancient Egypt* (part i., 1920) Prof. Flinders Petrie describes the hoard of personal ornaments found some ten years ago at Antinoe, in Upper Egypt. Unfortunately, the hoard was not preserved intact, and the valuables are now scattered in London, Berlin, Detroit, and the Pierpont Morgan collection. The greater part of the treasure, now described by Dr. Dennison, is dated by coins to the time between Justinian and Mauricius Tiberius, the latter half of the sixth century. The finest object is a great necklet with fourteen inserted coins from Theodosius to Justinian, and a barbaric imitation of a gold coin of Valentinian III. as a centre-piece, the taste for making imitations of coins for ornament being familiar in North Europe. Prof. Petrie attributes the dispersal of the collection to the present Egyptian law of treasure-trove. If the Government would pay, as dealers do, the local prices, collections could be purchased much below the value in Europe, and the profit would go to the State, not to the dealer.

The probability of the Norse discovery of Spitsbergen before the voyage of Barents in 1596 is the subject of an article by Dr. F. Nansen in *Naturen* for January–February, 1920. It has long been a matter for discussion whether the Svalbard of the Icelandic annals was Spitsbergen, and the weight of evidence favours the belief that it was. Dr. Nansen reproduces an Icelandic map published in the sixteenth century, before Barents's discovery, which certainly suggests that Svalbard was the coast of Spitsbergen. At the same time, it does not preclude the possibility of its identification with north-eastern Greenland; but this explanation is improbable, in view of the courses given for reaching Svalbard from Iceland. Dr. Nansen believes that the Norsemen found Svalbard by chance, some vessel having been driven out of its course by a gale. He thinks that the greater attraction of the fisheries on the coast of Norway, particularly the Lofoten Islands, diverted attention from Svalbard, which was eventually forgotten. There is no evidence whatever that Barents made any use of Norwegian knowledge in his voyage in 1596. The article contains a good reproduction of the map known as Barents's chart, published in 1599 by Cornelius Claesz.

A well-known and much-advertised institute of mind-training has sent us particulars of a laboratory of applied psychology which it has organised and equipped. For a specified fee the laboratory, it is stated, "will enable those who need vocational guidance to discover with scientific accuracy their strong and weak points, and to obtain expert advice on the choice of a career. . . . Those living at a distance can have tests forwarded by post." Vocational psychology is the youngest branch of the youngest of the sciences; it is not ten years since the publication of the well-known books by Taylor and by Münsterberg upon industrial psychology and so-called scientific management. Many, therefore, will doubt whether any laboratory can yet state the vocational qualifications of a given individual "with scientific accuracy" either by post or otherwise, much less whether an institute organised for profit is the proper place for such investigations. At the same time the new venture is a striking testimony to the advance made by psychology, both during and since the war, into fields of practical application; and, clearly and ably written as they are, the two pamphlets issued by the new laboratory, on "Choosing a Vocation" and on "Choosing Employees," may do useful service in acquainting both employers and applicants for employment with the possibility of scientific method in vocational guidance, and with the probability that, when established by disinterested research, such methods will be as superior to the current methods of personal preference or of phrenological advice as the prescriptions of a properly qualified medical specialist are superior to the pills of a wise grandmother or the potions of a local herbalist.

We have on several occasions referred to articles in the *Cologne Post*—a daily paper published by the

Army of the Rhine—on educational institutions and work connected with the Army of Occupation. The first number appeared on March 31, 1919, and a copy of the anniversary issue reached us a few days ago. The journal has been most successful, and is exerting a very valuable influence in revealing British thought and spirit to Germany. It has a large circle of German readers, and is used in many schools for reading lessons and the study of English. "Here," says an editorial article in the anniversary number, "in this great German city we bide, facing a wonderful land torn with dissensions after the mightiest conflict of all time; we of the *Cologne Post*—a little band of soldier scribes—and, never forgetting the ravaged west which lies behind us, we are facing east, where the sun rises." To the staff which is thus promoting a better understanding between two peoples we offer our most cordial congratulations upon the success of their faithful and intelligent work. It is particularly appropriate that we should associate ourselves with other good wishers in this expression, because Capt. W. E. Rolston, the editor and manager of the *Cologne Post*, was, before the war, a constant contributor to our columns. He was formerly an assistant to Sir Norman Lockyer in the Solar Physics Observatory at South Kensington, and when the observatory was transferred to Cambridge he went with it. For several years he wrote the whole of the notes in Our Astronomical Column, and also contributed numerous articles and reviews. Capt. Rolston provides another example of the value of a scientific training to business management and literary balance, and his devoted attention to what is really a unique newspaper merits the fullest official recognition.

IN a study of the colour and markings of pedigree Hereford cattle (*Journal of Genetics*, vol. ix., No. 3) Miss F. Pitt finds that the breed arose by selection from the nondescript cattle of the county during the seventeenth and early eighteenth centuries. All sorts of colours and markings prevailed, but among them the red with white face, which is still characteristic of the breed, was most common. This pattern probably originated through a mutation which appeared in a dark herd in 1750, and was kept and bred from as a curiosity. The white face is a dominant condition, while excessive white in modern Herefords is found to be recessive to the typical pigmentation. Variations from type which now occur in the breed are due to the outcrop of recessive characters inherited from the time before pattern selection was practised.

CONSIDERABLE foliage injury is reported in Michigan owing to the substitution of calcium and magnesium arsenates for lead arsenate for spraying purposes. The Quarterly Bulletin of the Michigan Agricultural College Experiment Station (vol. ii., No. 2, November, 1919) reports interesting tests carried out to discover the reasons for this injury. Plants in respiring give out considerable quantities of carbon dioxide, with which the film of moisture on the leaves is presumably charged. The tests show that calcium and magnesium arsenates are very much more soluble in carbonated water than in pure water, while for lead arsenate the reverse is true. It seems, therefore, that this solubility of calcium and magnesium arsenates in carbon dioxide is the cause of the foliage injury occurring in fruit-trees sprayed with these materials. It is suggested that the addition of lime to the spray mixture may prevent the injury, but this suggestion awaits proof.

As the result of comprehensive tests carried out by the New South Wales Department of Agriculture on two of their experimental farms, it is claimed that a more satisfactory method has been found of treating seed-wheat for bunt than by pickling in a bluestone solution. According to *Science and Industry* (Australia), carbonate of copper gives the best results, as has been shown after many years of experimenting with other substances. The method which the investigators recommend is to dust dry copper carbonate through the grain at the rate of 2 oz. of the fungicide to one bushel of wheat. Substantial increases in the yield per acre were obtained in comparison with pickled seed, while other advantages which the new process possesses over established practice are said to be that (1) no water is necessary; (2) no injurious effect is caused to either the grain or the young plant, as is the case with bluestone pickling; (3) seed-wheat can be treated weeks before it is sown; (4) no damage is done to the grain if it should lie in a dry seed-bed for weeks without germinating; (5) better germination is obtained; and (6) the process is quicker and less laborious than wet pickling.

AN Official Guide has been issued (143 pages, price 2s.) to the Museum of British Forestry (Museum No. 4) at the Royal Botanic Gardens, Kew. This museum, which was opened in 1910, occupies Cambridge Cottage, formerly the residence of the Duke of Cambridge. The term "forestry" is more correctly used as synonymous with sylviculture—that is, for trees and shrubs that are grown for commercial purposes—the term "arboriculture" being used for trees and shrubs that are grown as specimen plants or for purely ornamental work. The objects in view in the production of the two types of trees are very different, and the mature specimens differ in appearance. The scope of the museum is at present limited to collections of timber, fruits and seeds of trees, dried specimens of a few types of hardy trees and shrubs, photographs of isolated trees and plantations, the fungus- and insect-diseases of trees, articles manufactured from British-grown timber, and tools and machinery used in sylvicultural and arboricultural operations. In most instances the specimens shown have been grown, manufactured, or collected in the British Isles. Room No. 3 contains a series of special interest to the student, and illustrates the trees and shrubs native to or planted in Great Britain, with a brief account of their economic uses; the arrangement is according to the natural families. Injuries to trees caused by various agencies—animals, parasitic or climbing plants, fungi, and insects—are also illustrated in detail. Apart from its service as a guide to the museum, the booklet contains much

useful information on our British-grown trees and their economic value.

ATTENTION may be usefully directed to the high grade of Indian bauxites now under development, as represented by analyses given by Dr. L. L. Fermor in his article on "The Mineral Resources of the Central Provinces" (Rec. Geol. Surv. India, vol. l., p. 273, 1919).

DR. HOLTEDAHL's interesting maps and discussion of the distribution of land and water in the North Atlantic region in Palæozoic times (see NATURE, vol. ciii., p. 433) have been reproduced for readers of English in the *American Journal of Science* for January (vol. xlix., p. 1). Some corrections have been noted in the separate copies sent out by the author, the most important being the accidental exchange of the titles of Figs. 9 and 11, which should be rectified by those who may use them in their re-issued form.

IN a paper on "Old Age and Extinction in Fossils" (Proc. Geol. Assoc., vol. xxx., p. 102, 1919) Dr. W. D. Lang directs attention to the reluctance—perhaps better called indifference—of the female to the reception of the male animal, as exhibited, for instance, by mosquitoes, as a possible cause of extinction of a group. He applies this possibility to the ammonites; but his main thesis is that extinction may result from exaggeration of a structure on the removal of an inhibiting influence. Environment may thus be effective, but the tendency in the organism is, on the whole, superior to external influences in affecting evolution and decadence. The increase in deposition of calcium carbonate in the Cretaceous cheilostomata, and the "exhaustion of their ancestral potentialities" in the case of the rugose corals, are utilised as examples in a discussion that would obviously bear expansion.

SCIENTIFIC Paper No. 363 of the Bureau of Standards (Washington) just to hand deals with the manner of preparation and determination of the spectral reflective properties of certain alloys of aluminium with magnesium and with zinc by R. G. Waltenberg and W. W. Coblentz. The investigators found that all these alloys tarnish in time, and hence are not suitable for mirrors where permanency is of the first importance. The compound of aluminium and magnesium, Al_3Mg_4, deteriorates less rapidly than any of the other alloys examined, and could be used in apparatus where a highly reflecting mirror is desired for a short time. A reflectivity of 92 per cent. at 0.7μ was obtained with this compound. The zinc-aluminium alloy has a minimum reflectivity at 0.9μ. An examination of the reflectivity of pure zinc revealed a similar reflectivity minimum at 0.1μ.

IN a paper on "The Development of the Atomic Theory," by A. N. Meldrum, of the Bombay University, published by the Oxford University Press, a plea is put forward that historical questions should be made the subject of serious investigation and discussion, and should be taught in the universities by those who have given special attention to them. The paper is devoted very largely to vindicating the view that the atomic theory was not originated as a pure novelty by Dalton, but was a legitimate development of Newton's views. Attention is directed to the importance of Newton's theory of the repulsion of gaseous particles in the theoretical views of Bryan Higgins, William Higgins, and Dalton. Thus Bryan Higgins suggested that ammonia and hydrogen chloride must unite particle with particle, and in no other way, since if two particles of ammonia attempted to combine with a single particle of acid, one of them would be driven away from the acid by the mutual repulsion of the two particles of ammonia. William Higgins, for the same reason, assumed that, since like atoms repel one another, the most stable combination of dissimilar atoms is in the ratio 1:1, then 2:1, and then 3:1. This view did not attract so much attention as it deserved, but was identical with the method used by Dalton in deducing the formulæ of compounds. It is suggested that Dalton did not necessarily borrow his views from Higgins, but that both workers, starting from Newton's doctrine of an elastic fluid composed of mutually repulsive particles, followed much the same train of thought and reached essentially the same conclusions.

PROF. AIMÉ WITZ, professor of physics at Lille University, contributes a well-reasoned article on heat economy to the issue of the *Revue générale des Sciences* for March 15. He reviews in turn the merits of steam-engine and turbine plants, internal-combustion engines, and electric power distribution from the point of view of thermodynamic efficiency. As regards the reciprocating steam engine, he counsels caution in the replacement of this method of heat utilisation by turbo-electric plants in small works, and cites figures to show that the *generic* efficiency of the former may be extremely favourable under certain conditions. Much progress has been effected in recent years in the design of exhaust steam turbines, and in certain cases it may be very desirable to run a low-pressure turbine off the large cylinder of a multiple expansion steam engine of the reciprocating type, and thus effect a better yield per pound of steam expended. On the wider (national) question the author devotes considerable space to the subject of the gasification of coal at the place of production and its direct utilisation for power purposes, with the recovery of by-products, the gas generated being used for running large gas engines, and the heavy residual oils for internal-combustion engines of the Diesel type. In this connection he gives some figures showing the very satisfactory results obtained at certain mines in France from installations run from coke-oven gas, supplemented by steam units, for power purposes. Finally, he reviews the claims for a national electric network, comprising a number of single and self-governing units combined to meet all the possible demands of industry. The paper is well worthy of study by all who are interested in the better utilisation of our fuel resources.

Our Astronomical Column.

CONJUNCTION OF JUPITER AND NEPTUNE.—On the morning of April 20 these planets will be within 1° of each other; the actual distance at 4 a.m. will be 0° 55′, Jupiter being on the north side of Neptune. Jupiter will set at 2.37 a.m. The motion of the two objects is so slow that in the earlier hours of the night of April 19 their relative positions will be but slightly different from that at the time of conjunction on April 20 at 4 a.m. Neptune will be situated in Cancer about 2¾° east-south-east of the star cluster called Præsepe and 1⅓° east of the star δ Cancri. Neptune may be easily picked up in a good telescope, but is not brighter than about eighth magnitude. To identify this faint object if the small stars north of Jupiter are unknown requires that the observer should make a diagram of the objects in the field of the telescope and compare it with later observations in a few weeks' time. At the period of conjunction Neptune will be stationary.

A NOVA IN A SPIRAL NEBULA.—*Ast. Nach.*, 5038, contains a note by Prof. Wolf on the discovery of a nova in the faint spiral nebula N.G.C. 2608 (position for 1860, R.A. 8h. 26·7m., N. decl. 28° 56′). The nebula is shaped like the letter S; the star is near the left-hand point of the upper curve. There are two nuclei, of which the north preceding is the brighter. The nova is 18·6″ from this nucleus, in P.A. 280°. It was discovered on a plate taken on February 8 last, and was afterwards found to be registered faintly on plates taken on January 25 (near edge of plate, bad image) and February 7. Plates taken in previous years were examined, and showed no trace of the star; a small nebular condensation was, however, visible in the neighbourhood. The latest available plate was taken on 1918 February 5.

Short exposures were secured of the nebula on February 11 and 12; the nova appeared brighter visually on the former date. On the latter its photographic magnitude was 10·7. A sketch-map of the field is given in *Ast. Nach.*, with magnitudes of comparison stars. It is important to obtain good light-curves of these novæ in spirals, as they sometimes give a clue to the absolute magnitude of the star, and hence of the distance of the spiral. The region will be observable for the next two months.

Observations on March 10 gave the magnitude of the nova as 11·5.

THE MADRID OBSERVATORY.—The "Anuario del Observatorio de Madrid para 1920," in addition to the usual almanac information, particulars of the sun-spots and prominences in 1918, and meteorological observations, contains a useful article by Señor C. Puente on methods of determining time and latitude by means of portable instruments in the field. Special attention is directed to the circumzenithal telescope designed by Nušl and Frič, of Prague, which consists of a small horizontal telescope which can be rotated in azimuth. A silvered prism with vertical angle α is mounted outside the object-glass; the upper face reflects light from a star of altitude $180° - \alpha$, the lower face light from the same star after reflection by a very small mercury trough. Coincidence of the two images is observed in the telescope, and gives the instant when the star's altitude is $180° - \alpha$. There are some advantages in making this angle equal to the latitude, but this is not essential. Tables are given facilitating the construction of working catalogues. Observations of several known stars make it possible to deduce both time and latitude. The instrument is similar to the almucantar in theory, but far more portable and easier to work with. The absence of all webs and screws is a decided advantage.

National Education.

THE fiftieth annual meeting of the National Union of Teachers, founded in 1870, at which some 2000 delegates were present, representing a membership of 113,000 as compared with 400 on its formation, was held during Easter week at Margate. The proceedings were opened by a well-timed and thoughtful address on the part of the new president, Miss J. F. Wood, of the Fielden School, Manchester (herself a pioneer in the endeavour to bring opportunities of advanced secondary education within the reach of children leaving school during their fourteenth or fifteenth year), in which she reviewed the history of popular education since the Act of 1870, recounting its onward progress and making clear the objects still to be achieved, to ensure which all the various classes of teachers should make a common effort and present a united front. The Act of 1918, with which the name of Mr. Fisher will be linked in honour for all time, provides for fuller opportunities of education for elder children in elementary schools, for their easier transfer to higher schools by means of maintenance grants, for closer attention to conditions of physical health and education, and especially for the continued part-time education up to eighteen years of age of adolescents entering industrial life at fourteen.

The president pleaded for a more unified conception of education if these objects are to be attained and the full value of education to the nation is to be realised. Every child capable of profiting by advanced courses of education and training, whether given in higher or special schools or in the universities, should be afforded the fullest facilities. Wherever possible the elementary school should be enlarged in scope, with freedom to develop its own "top," and so obviate the necessity for the establishment of the central school with its futile two-year course. The further education of adolescent workers should have careful consideration, and, having regard to the mechanical nature of much of their work, also have in view the claims of leisure. With the purpose of fitting the primary teacher for all branches of education service, including the administrative, he should in all cases, in addition to appropriate professional training, be also required to take a university degree. The claim of women to be afforded equal opportunities with men to aim at the highest in the career they enter and with the same reward was firmly stressed. The future progress of education depends not only upon more suitable buildings, adequate playgrounds and equipment, and smaller classes, but also upon the supply of able and well-educated teachers, who must be attracted first by the nature of the work, and then by adequate pay, status, and prospects. There should be ensured also the full co-operation of the Board of Education, the local education authorities, and the teachers with the view of securing full partnership in administration, and, above all, of winning for all children a free and liberal education.

Among the many important topics discussed during the conference, reference may be made to that dealing with a national system of education, which received the full assent of the conference, and embodied proposals for (1) free education for all to the fullest extent of their capacity to profit by it; (2) the provision of maintenance grants where necessary; (3) the due co-ordination of schools, so that graduation from one to another of higher type shall be easy; (4) uniform regulations for all schools in respect of size of classes, adequacy of staff, floor- and air-space, playing grounds and fields, and swimming baths; (5) medical examinations, and treatment where neces-

sary; (6) the right of any qualified teacher to teach in any capacity in any State-aided school; (7) no class in any type of school to exceed thirty on the roll, and each class to have its own qualified teacher; and (8) the curriculum of the primary school should be liberal and non-vocational, with the aim of promoting true citizenship and high personal character. It was also suggested that the attention of public opinion and of organisations representing parents of elementary-school children should be directed to the powers now possessed by persons interested in education to secure substantial improvements in the educational facilities provided in their localities by means of representations on the schemes prepared by local education authorities under the Act of 1918, where such schemes fail to attain the standard set up in the foregoing proposals, and that county and local teachers' associations should stimulate the demand for the full benefits of the Act of 1918 in each locality.

A further important topic discussed at the conference was "The Supply and Training of Teachers." The scheme submitted was approved by the conference, and included the following main requirements: (1) All intending candidates should have completed a satisfactory course of higher education, and show by adequate tests their fitness for the profession; (2) the admission to the graduate course should be the standard of matriculation; (3) the course of study should include "Education" as a principal subject for the degree, and the course be followed in association with other students entering for other professions; (4) a period of one year should, as a rule, be devoted to the acquisition of skill in teaching, the existing training colleges (which should be recognised as colleges of the university) being utilised for this purpose alone, whilst education research work should be a distinct feature of the college staff, and students; (5) on the completion of the academic and professional training the teacher should be eligible for recognition by the Board of Education for service in any approved school; and (6) the teachers of special subjects should be required to take a course of higher education and of professional training.

Aeronautics at the Imperial College.

SIR RICHARD GLAZEBROOK, the occupant of the Zaharoff chair of aeronautics at the Imperial College of Science and Technology, completed on March 24 the series of five lectures which initiate the new course of study. It will be remembered that Sir Basil Zaharoff founded similar chairs in Paris and in Petrograd. The London chair has been chosen by the Government as the nucleus around which to organise a central school of aeronautics—a scheme in which the new professor's long experience as Director of the National Physical Laboratory, chairman of the Advisory Committee for Aeronautics, and, latterly, chairman of the Government Committee on Education and Research in Aeronautics, will be of immense help. In the years to come the courses of instruction so provided will doubtless prove of service to officers of the Royal Air Force selected by the Air Ministry for higher technical training, in addition to such numbers of other students as the then position of civil aviation may inspire to join this new and adventurous profession.

The attendance at this initial course of lectures must have been encouraging to the lecturer, if only as an indication of a widespread general interest in the subject. In the circumstances, the lectures were, naturally and rightly, of a simple character, only the last one, on air-screws, being at all technical.

Sir Richard Glazebrook in his first lecture paid a tribute to the munificence of the founder of his chair, and proceeded to a description of the experimental wind-channels and of full-scale experiments on aircraft. He was able to show how, on Lord Rayleigh's law of similarity, the measurements made by the one method could be compared with the other. The agreement in most cases was reasonably satisfactory, though enough anomalies had been found to provide an ample field for future research work. This was followed by a lecture on the principles of automatic and inherent stability. The former is achieved by the use of auxiliary apparatus, whether mechanical or aerodynamic, to operate the controls of the machine; and the latter by providing, in the original design, such sizes and positions for the aerodynamic surfaces that any departure of the machine from its normal position brings into play forces which tend to restore it to that position, and create a "damping" couple sufficient to prevent the continuance of such oscillations. Inherent stability can, as experience has amply shown, be provided for by careful design, so that automatic apparatus for the purpose is quite unnecessary. Commercial machines should be decidedly stable, fighting machines only just stable. Sir Richard Glazebrook was able to show (with Mr. Nayler's assistance) a number of mica models in flight, and so to illustrate the various forms and degrees of stability and instability.

The third lecture was concerned with the instruments essential to flight, and included the air-speed indicator, the engine-revolution indicator, the altimeter, the clinometer (to indicate side slip), the statoscope (to show the rate of climb), and the turn indicator. The statoscope measures the rate of air leakage through a small hole in a vessel kept at a constant temperature. Turn indicators are of two forms, the static head type and the precessional gyro type; these are later inventions than the other instruments mentioned.

Among the most important measurements made on an aeroplane are the determinations of oscillation in yaw, roll, and pitch; for such experiments use can conveniently be made of the sun as a fixed point, since the motion of a shadow of some part of an aeroplane on the rest of the machine can be employed to obtain a photographic trace of the oscillations. This work, however, is really only just beginning.

In view of the enormous inertia forces which come on a machine when "stunting," it is essential to obtain a continuous record of their amount during all parts of the flight-path concerned. For this purpose a stiff fibre acted as an acceleration index, and some most valuable records were obtained. On occasion the force on the wings of the machine might be three, or even four, times the weight of the aeroplane.

This naturally led in the fourth lecture to a consideration of the strength of the wing structure and to statements of the load factors necessary in design. The load factor is the ratio of the breaking load to the normal load corresponding to horizontal straight flight at the designed speed. Another important coefficient is the factor of safety, and this is the ratio of the breaking load to the loading incurred during some specified operation, *e.g.* a vertical nose-dive. The load factor needs to be fixed at a higher figure for machines which, like fighting machines, have to "stunt."

Sir Richard Glazebrook's fifth and last lecture was of special interest. The subject, "Air-Screws,"

is intricate, and not one in which it is easy to excite interest in a general audience. It is, therefore, much to the lecturer's credit that he succeeded in making the subject not only intelligible, but also interesting. He discussed first Froude's theory of the screw, and then showed how the various factors in the resulting equations had been checked by experimental work both in the wind-channel and on the "rotating arm" apparatus. Incidentally, he referred to the flapping flight of birds, showed how difficult it would be to imitate this, and doubted whether true progress lay in this direction. Mankind had made much use of the wheel in mechanism; evolution had led to the introduction of no such element in animal life, in spite of its proved efficiency in its many human applications. This afforded an argument that man had here beaten uninstructed Nature. The only flying animal which approached the aeroplane in design was perhaps the beetle, which possibly used its horny wing-covers as stationary planes and its wings as a means of propulsion.

The Parallaxes of Globular Clusters and Spiral Nebulæ.

It may be remembered that Dr. Charlier expressed doubt as to the correctness of the enormous distances for globular clusters announced by Dr. Harlow Shapley. Mr. Knut Lundmark, of Upsala Observatory, undertook a re-examination of the question, taking different lines of evidence from those used by Dr. Shapley. His work is published in *Kungl. Svenska vetenskapsakademiens Handlingar,* Band 60, No. 8. His data are avowedly of a much less precise character than those used by Dr. Shapley, but they lead to results of the same order of magnitude:—

(1) The discussion of the proper motion of those clusters for which data are available indicates a value not exceeding 1″ per century. Accepting this maximum value, and combining it with the mean radial velocity of clusters found by Prof. Slipher, Mr. Lundmark finds the distance 3000 parsecs, one-fifth of Dr. Shapley's value.

(2) Use is made of Kapteyn's luminosity law. Van Schouten has already applied this method to the clusters M3, 5, 11, and 13, obtaining distances that are, in the mean, twenty-eight times those of Dr. Charlier and one-eighth of those of Dr. Shapley. His work is here revised, estimation being made of the spectral type of the stars from Dr. Shapley's observed colour-indices. The mean of several independent estimations gives 6000 parsecs for the distance of M3 and M13.

(3) A rough estimate of distance is made from the observed mean absolute magnitudes of stars of different spectral types. Various assumptions are made as regards the mean spectral type of the stars employed. In the mean the distances found are about eighty times those of Dr. Charlier, or one-third of those of Dr. Shapley.

(4) Holetschek has investigated the apparent magnitudes of several clusters regarded as single objects. Mr. Lundmark shows that his values are about 7½ magnitudes brighter than Dr. Shapley's mean values of the twenty-five brightest stars in the respective clusters, this difference being very nearly constant.

It follows that the assumption that the absolute magnitude of a cluster is constant will lead to relative distances of the different clusters proportional to those deduced by Dr. Shapley.

The four lines of evidence outlined above, though individually weak, have cumulative force, and tend to increase confidence in the accuracy of Dr. Shapley's work.

Mr. Lundmark uses Prof. Slipher's radial velocities of clusters to determine the sun's motion with regard to them. He finds that its velocity is 381 km./sec. towards R.A. 320°, N. decl. 74°. He notes that both the R.A. and declination of the solar apex as determined from stars tend to increase as fainter stars are used. This is explained by a larger proportion of the stars being outside the local cluster. He suggests that his value is the limit to which the others are tending.

Mr. Lundmark passes on to consider the parallaxes of the spiral nebulæ.

(1) Beginning with the Andromeda nebula, he quotes all the directly observed measures of its parallax. They are discordant, but their mean is near zero.

(2) The star density increases towards the middle of the Andromeda nebula, in spite of the nebulosity tending to veil them. It is concluded that the nebula is more distant than the non-nebular faint stars in the region. A combination of the results of many workers indicates a distance of 3000 parsecs for these faint stars.

(3) A combination of measured angular rotation of spirals with the values of the linear rotational speed given by the spectroscope has led to estimates of distance somewhat greater than the last, say 4000 parsecs. It is further shown that the mass necessary to control the rotation is $10^9 \times$sun, of the same order as the estimated mass of the stellar system.

(4) Making the rather doubtful assumption that the dark curves in various nebulæ have the same absolute dimensions as the similar dark regions in the galaxy, Wolf finds distances for various spirals ranging from 10,000 to 200,000 parsecs.

(5) Comparisons of the light curves of novæ in spirals with those in the galaxy, while they involve several rather doubtful assumptions, give very large distances for the spirals, 200,000 parsecs being found for the Andromeda nebula. Bullialdus noted that the Andromeda nebula was exceptionally bright in the year 1664. It is conjectured that a nova of magnitude 5 or 6 may have appeared in it at that time.

From the above and other considerations Mr. Lundmark locates the spiral nebulæ far beyond the galactic limits, but inclines to the view that they are the star-producing mechanisms of Mr. Jeans's theory rather than counterparts of the galaxy. Their linear dimensions appear to be much inferior to the latter, of which our ideas have lately been enlarged by Dr. Shapley's and other researches.

The Forestry Commission.

We are informed that the Forestry Commissioners who were appointed on November 29 last at once proceeded with the planting programme for 1919–20. The shortage of forest-tree seed has been met to a great extent by purchases in Austria and elsewhere and by gifts from the United States and Canada. About 34,000 acres of afforestable land are in course of acquisition by purchase or on lease, in some cases below the market value and in others as free gifts from landowners. Rather more than 10,000 acres are in England, of which 3500 are in Suffolk, 2760 in Devon, 1150 in Cumberland, and 1800 in Northamptonshire and Bedfordshire. More than 5000 acres are in Ireland, of which 2000 are in Tyrone, 1500 in County Galway, 1500 in King's County, and

the remainder in County Cork. The remaining 18,000 acres under acquisition are in Scotland. Planting is proceeding at thirteen centres—six in England and Wales, six in Scotland, and one in Ireland. Statistical work is being carried out and preliminary surveys are being undertaken.

The scheme for advances under the Forestry Act will be published after the consultative committees which have just been set up have considered the proposals.

Forest apprentices are receiving a two-year course in the Forest of Dean, the New Forest, and in Chopwell Woods, near Newcastle, and additional schools will be opened during the year. A special course for men with previous forestry experience is being conducted at Marischal College, Aberdeen.

An Imperial Conference to consider the forest resources and policy of the Empire is being organised for July, when a number of persons interested in forestry are expected in this country for the British Empire Timber Exhibition. The conference is expected to lead to the establishment of an Imperial Bureau of Forestry Information.

The Commission has published Bulletin No. 1, "Collection of Data as to the Rate of Growth of Timber" (which can be obtained post free for 4½*d.* on application at the headquarters of the Commission, 22 Grosvenor Gardens, London, S.W.1); also Leaflet No. 1, "Pine Weevils" (free). Other publications will follow at an early date.

The four consultative committees under the Forestry Act have been appointed, and consist of the following members:—

England.—Lt.-Col. G. L. Courthope (chairman), Col. M. J. Wilson (vice-chairman), Sir J. Ball, Lord Henry C. Bentinck, E. Callaway, the Earl of Chichester, M. C. Duchesne, J. H. Green, W. A. Haviland, Sir Edward Holt, Bart., E. C. Horton, A. F. Luttrell, W. Peacock, Major Harold Pearson, Col. B. J. Petre, Thomas Roberts, Sir William Schlich, W. R. Smith, Charles Stewart, Sir Lawrence Weaver, Col. J. W. Weston, and Leslie S. Wood.

Wales.—The Lord Kenyon (chairman), Col. F. D. W. Drummond (vice-chairman), C. B. Bovill, Major David Davies, Alderman T. W. David, Col. J. R. Davidson, Capt. J. D. D. Evans, Col. W. Forrest, Vernon Hartshorn, G. A. Humphreys, C. Bryner Jones, J. Jones, Lt.-Col. W. N. Jones, Col. C. V. Llewellyn, F. J. Matthews, the Earl of Powis, L. R. Pym, D. C. Roberts, J. Roberts, Major-Gen. A. E. Sandbach, J. I. Storrar, the Lord Tredegar, H. C. Vincent, P. Wilkinson, and Col. Sir H. L. Watkin-Williams-Wynn, Bart.

Scotland.—Sir Hugh Shaw-Stewart, Bart. (chairman), Gen. Stirling of Keir (vice-chairman), the Right Hon. William Adamson, Sir Isaac Bayley Balfour, F. R. S. Balfour, Wm. Black, Gilbert Brown, J. C. Calder, Sir Isaac Connell, J. A. Duthie, G. Fraser, R. Galloway, S. J. Gammell, Sir Robert Greig, J. H. Milne Home, G. Leven, Sir Robert Lorimer, H. L. Macdonald, Sir Kenneth J. Mackenzie, Bart., J. T. McLaren, J. Matson, D. Munro, Major W. Murray, J. Scott, and J. Wight.

Ireland.—T. B. Ponsonby (chairman), H. De F. Montgomery (vice-chairman), E. M. Archdale, J. Bagwell, the Lord Osborne Beauclerk, R. Bell, R. Bradley, S. Brown, J. R. Campbell, St. Clair M. Dobbs, Sir Henry Doran, J. Everett, V. C. Le Fanu, Wm. Field, A. C. Forbes, J. Calvin, the Earl of Granard, Prof. Augustine Henry, Wm. Kirkpatrick, A. E. Moran, the Viscount Powerscourt, the Viscount de Vesci, A. Vincent, Capt. R. H. Prior Wandesforde, and the Right Hon. F. S. Wrench.

Recent Fishery Investigations.[1]

FIVE years ago the pivot round which fishery investigation turned was the question of the productivity of the North Sea grounds. It was agreed that the enormous development of catching power since the last third of the nineteenth century had produced no apparent change in the abundance of herring, haddock, whiting, and possibly some other species, but that, on the other hand, plaice, sole, turbot, and some other edible fishes had been affected. In January, 1913, the Plaice Committee of the International Fishery Council stated that it then had evidence that large plaice were becoming scarcer in the North Sea, and that small plaice were becoming more abundant, and this was taken to be proof that there was "impoverishment," or excessive exploitation of a natural resource. The conclusion is not free from ambiguity, for, on the whole, the *total quantity* of fish landed increased up to 1913; what had happened, it appears, was a reduction in the average expectation of life of a plaice living in the North Sea. Now if that change was a result of "intensive" fishing up to 1914, what has been the result of the very great decrease in fishing during the years 1915–18? Drs. A. C. Johansen and Kirstine Smith seek to answer this question by discussing measurements of plaice landed from a Danish North Sea area which was tolerably free from military restrictions during the period of war. They find that the pre-war tendency has been reversed; that large plaice are now relatively much more abundant than they were, but that their rate of growth has decreased—a curious result. We were justified, they say, in concluding that intensive fishing could reduce a natural stock of fish, and we are also justified in expecting that a slackening of this intensity of fishing, even for a relatively short period, will have the opposite effect.

The method by which the latter conclusion is made is indirect, and one is scarcely convinced that it is beyond doubt. It seems easy to show whether or not a natural fishery is stationary or declining. It would be easy and the conclusions certain if the systems of collecting statistics were adequate and well planned and if there were good scientific investigations that enabled one to interpret the statistical data. But the statistics are not adequate, and the scientific investigations have been neither well planned nor properly supported, and therefore the methods are roundabout ones and the conclusions do not carry absolute conviction. We do not know, for instance, that there is not a natural periodicity of abundance and that the results noticed do not simply represent phases in a cyclic change. It is quite likely that they do.

The last report of the Dove Marine Laboratory (at Cullercoats, Northumberland) contains an account (by Mrs. Dorothy Cowan and Mr. B. Storrow) of investigations into the local herring fishery. This and former reports contain a very rich series of data with regard to the biology of the herring on the North East coast, and apparently not all the results obtained have been published—the present report, for instance, deals only with age-determinations (by means of "scale-readings"), while biometric measurements made as part of the Board of Agriculture and Fisheries scheme of racial investigations have also been accumulated. Prof. Meek, in editing the report, points out that extensive accumulations of data have not yet been analysed, and that such treatment is advisable before further investigations are planned. His discussion of some of Mr. Storrow's results gives point to an expression of dis-

[1] "Meddelelser fra Kommissionen for Havunder sogelser; Ser Fiskeri," Bd. v., Nr. 9. (Copenhagen, 1919.)

appointment that the numerous inquiries and conferences held during the past year have not yet had any result. Local investigation with regard to the movements of herring shoals is insufficient. In this case the shoals leave Northumbrian waters and appear later on off the Firth of Forth, where, apparently, they are not sampled or investigated. It is therefore regrettable, Prof. Meek suggests, that reconstruction should have been a departmental rather than a national affair.

J. J.

Flora of the Hawaiian Islands.

THE natural history of the Hawaiian Islands has been well worked as regards both the flora and the fauna. Generally speaking, there is an extraordinary degree of endemism in the plants and animals, associated with a strong Southern Pacific or Australasian and Indo-Malayan affinity and a weak Northern Pacific or American affinity. The islands are extremely isolated, being further removed from any continental area than is any other region of equal size upon the globe. The nearest continent is North America, two thousand miles away, and the nearest islands of any importance, the Marquesas, are 1860 miles distant. Within forty miles of the shores the ocean exceeds 10,000 ft. in depth, and between the islands and the American coast reaches in places more than 20,000 ft. The most commonly accepted view of the origin of the archipelago is that the islands, which are entirely volcanic, were raised by volcanic activity, and that they have always been completely isolated.

In a paper entitled "The Derivation of the Flora of Hawaii" (Leland Stanford Junior University Publications, University Series, 1919) Prof. D. H. Campbell gives a *résumé* of the composition of the flora and its relations to American and Southern Pacific floras generally, and criticises unfavourably Guppy's view of its origin and distribution. Guppy accepts the view that the archipelago has always been completely isolated, and that air-currents and birds have been the agents concerned in its population. The predominantly Australasian and Indo-Malayan element was, he suggests, introduced largely by birds, especially fruit-eating pigeons, but Prof. Campbell finds a serious objection in the absence of such birds from the present fauna, as, apart from a number of American migratory shore-birds, practically all are endemic. Prof. Campbell strongly supports the view taken by Mr. H. A. Pilsbry, based on the study of the molluscan fauna. The land-snails are all ancient types the modern representatives of which are largely confined to Polynesia, and they represent, it is contended, an ancient fauna which has survived from a time when Hawaii was part of a continental area connected to the south-west with that of Polynesia. A study of the insects leads to a similar general conclusion, namely, that while the ancestors of some of the species may have been introduced through the agency of wind- or ocean-currents or by migratory birds, there are many more species of both plants and animals the presence of which can best be explained by a former more or less direct land-connection between Hawaii and the Indo-Malayan region.

The multitude of islands constituting Polynesia are, on this hypothesis, the remains of a once extensive land-mass, either a single continent or several large continental islands like Australia. This great area has been subsiding since Early Tertiary times, and the existing islands are the tops of mountain masses, often volcanic, superimposed upon this submerged continental area. A serious objection to this theory is the absence in Hawaii of certain types of vegetation characteristic of Southern Pacific regions, such as the conifers, aroids, and figs, and it is suggested that these forms became extinct after the isolation of the islands. Similar examples of such disappearance of plants are afforded by Sequoia, Liriodendron, and other genera, which had once a wide distribution, but are now represented in many regions only by Tertiary fossils.

University and Educational Intelligence.

DR. J. B. CLELAND, of the Health Department of New South Wales, has been appointed to fill the newly constituted chair of pathology in the University of Adelaide, South Australia.

APPLICATIONS for grants from the Dixon Fund, of the University of London, for assisting scientific investigations, are receivable by the Academic Registrar, University of London, South Kensington, S.W.7, until May 14 next. They must be accompanied by the names and addresses of two referees.

THE MARQUESS OF CREWE, chairman of the governing body of the Imperial College of Science and Technology, and Sir Alfred Keogh, Rector of the college, will attend the annual dinner of the Old Students Association of the Royal College of Science, to be held at the Café Monico on Saturday, April 24. Other distinguished guests will be Prof. W. H. Bragg, Dr. W. Garnett, Sir Richard Glazebrook, Mr. W. McDermott, and Sir Ronald Ross. Tickets (price 10s. 6d.) may be obtained from Mr. C. S. Garland, acting secretary, Old Students Association, Royal College of Science, South Kensington, London, S.W.7.

AT a general meeting of old students held recently at King's College, Strand, it was decided to form a King's College, London, Old Students' Association for the purpose of promoting social intercourse and of keeping the members in touch with their old college. The association hopes to include students from all faculties, and the subscription of 10s. 6d. per annum will include the *King's College Review*, published once a term, and a list of members with their addresses (and possibly the work on which they are engaged). Further particulars and forms of application for membership may be obtained from Miss M. A. V. Fairlie, hon. secretary, 3 St. Julian's Farm Road, West Norwood, S.E.27.

Societies and Academies.

Faraday Society, March 1.—Dr. T. Martin **Lowry** and F. C. **Hemmings**: The properties of powders. The caking of salts is, in general, dependent on the presence of a solvent, usually water. The following cases have been studied: Nitrates, other anhydrous compounds, hydrated salts, loss of sulphur dioxide during caking, and contraction during caking of copper sulphate.—Dr. T. Martin **Lowry** and S. **Wilding**: The setting of dental cements. Phenomena of caking or setting may be divided into five classes:—(1) Recrystallisation of anhydrous or hydrated salt without change of chemical composition. (2) Formation of hydrates. (3) The hydrolysis of complex salts by water. (4) The formation of new salts, such as the magnesium oxy-cements and the zinc oxy-phosphate cements used in dentistry, and "silicate" cements. (5) Amalgams in which mercury takes the place of water.

Zoological Society, March 16.—Prof. E. W. MacBride, vice-president, in the chair.—R. I. **Pocock**:

External characters of the South American monkeys. The paper showed the variations in the range of structure of the ears, nose, hands, feet, and external genitalia.—Dr. C. F. **Sonntag**: The comparative anatomy of the tongues of the mammalia. Having first outlined the plan which would be followed in his series of comparative studies, the author proceeded to describe the different divisions of the tongue and the physical characters of each. He demonstrated by diagrams and lantern-slides the different forms which the papillæ and openings of Wharton's ducts can assume among the mammalia, and exhibited specimens illustrating the shapes and colours of the tongue and the arrangements for cleaning the teeth.

March 30.—Dr. A. Smith Woodward, vice-president, in the chair.—Dr. C. F. **Sonntag**: Abnormalities of the abdominal arteries of a young panda.—A. **Loveridge**: East African lizards collected in 1915–19, with description of a new genus and species of skink and a new sub-species of gecko.

Royal Meteorological Society, March 17.—Mr. R. H. Hooker, president, in the chair.—Capt. C. K. M. **Douglas**: Clouds as seen from an aeroplane. A large number of photographs of clouds taken from an aeroplane were shown, nearly all of which were taken by the lecturer while flying in co-operation with the Meteorological Section, R.E., in France in 1918–19. The primary object of the flights was to obtain the temperature in the upper air for the artillery and for forecasting, and advantage was taken of the opportunity to study cloud-structure and its relation to the upper-air temperature and humidity and to the general meteorological conditions. The observations were made at Berck, on the French coast, twenty miles south of Boulogne, which lies close to the most important aerial routes. The photographs showed a large variety of cloud-forms, and also some changes which took place in short periods. A number of the photographs showed thunderclouds. Thunderstorms are caused by powerful ascending currents, and the tops of the clouds grow up to a great height, frequently exceeding 20,000 ft. Often when the weather is overcast and gloomy there is brilliant sunshine within one or two miles of the ground, and the clouds viewed from above present a splendid spectacle.

PARIS.

Academy of Sciences, March 8.—M. Henri Deslandres in the chair.—G. **Humbert**: An extension of the modular group in an imaginary quadratic body.—F. E. **Fournier**: Forms of hull of least resistance to their translation in free air at all velocities.—C. **Guichard**: A characteristic property of congruences belonging to a linear complex.—P. **Vuillemin**: Remarks on a fungus attributed by M. Loubière to the genus Trichosporium.—Sir James Dewar was elected a correspondant for the section of general physics in succession to the late Prof. Blaserna.—J. **Villey**: The adaptation of internal-combustion motors to high altitudes.—B. **Gambier**: Surfaces of translation applicable to each other.—M. **Fréchet**: A complete family derived from the family of ensembles "*bien définis*."—P. **Humbert**: Functions of the parabolic hypercylinder.—M. **Renaux**: A problem of iteration.—J. K. **de Feriet**: An application of generalised differentials to the formation and integration of certain linear differential equations.—L. **de Pesloüan**: The extension of the rule of L'Hôpital to certain arithmetical quantities.—J. **Chazy**: The impossible singularities of the problem of *n* bodies.—H. **Blondel**: Application of the method of Lagrange to the orbit of the planet discovered by M. Comas Solà, January 13, 1920.—E. **Belot**: A new form of the law of distances of planets and satellites resulting from the spiral formation of the planetary system, and the cause of rotation of the planets.—J. **Guillaume**: Observations of the sun made at the Observatory of Lyons during the third quarter of 1919. Observations taken on eighty-nine days are summarised in three tables showing the number of spots, their distribution in latitude, and the distribution of the faculæ in latitude.—L. **de Broglie**: The calculation of the limiting frequencies of K and L absorption of the heavy elements. A comparison of the numbers deduced from Bohr's theory and from Végard's formula with the average experimental data derived from the experiments of Végard, Siegbahn, and de Broglie. The results for the L bands for tungsten, platinum, gold, lead, bismuth, thorium, and uranium are clearly in favour of Végard's formula.—M. **Rennesson**: The loss of energy in the dielectric of commercial cables. Two sets of experiments are described: in the first the frequency and temperature were maintained constant, and the voltage varied; and in the second the temperature was the variable, voltage and frequency being constant. In the latter case the energy losses in the dielectric showed a minimum at 30° C.; the losses at 30° C. were about half those found at 12° C. or at 55° C.—A. **Caillas**: The search for invertin in pure honey. The presence of invertin in pure honey was definitely proved, and this explains why two analyses of a sample of honey made at different times may give different results for the sugars present.—J. **Martinet** and O. **Dornier**: The azo-compounds of indoxyl.—Ch. **Boulin** and L. J. **Simon**: The preparation of methyl chloride and bromide starting from dimethyl sulphate. The interaction of concentrated hydrochloric acid and methyl sulphate gives pure methyl chloride; methyl bromide is obtained in a similar manner by substituting a solution of an alkaline bromide acidified with dilute sulphuric acid for the hydrochloric acid.—M. **Zeil**: The ascensional movements of the earth's crust and the anomalies of gravity.—G. **Denizot**: The lower peneplain of the Paris basin.—R. **Abrard**: A layer of eruptive rocks at Souk el Arbâa du R'Arb (Western Morocco).—V. **Bjerknes**: The relation between the movements and temperatures of the upper layers of the atmosphere.—L. **Besson**: The primitive form of atmospheric ice.—C. E. **Brazier**: The variation of the indications of the Robinson and Richard anemometers as a function of the inclination of the wind.—A. **Guilliermond**: The figured elements of the cytoplasm.—J. D. **d'Oliveira**: The transmission of fasciation and dichotomy as a result of the grafting of two Portuguese vines.—J. **Magrou**: The immunity of annual plants towards symbiotic fungi.—J. E. **Abelous** and L. C. **Soula**: The cholesterinogenic function of the spleen.—J. L. **Dantan**: Oyster beds: their development, classification, and exploitation.

March 15.—M. Henri Deslandres in the chair.—G. **Humbert**: The groups of M. Bianchi.—Em. **Bourquelot** and M. **Bridel**: The detection and characterisation of glucose in plants by a new biochemical method. The production of methyl glucoside by the action of emulsin forms the basis of the new method proposed.—MM. **d'Arsonval, Bordas,** and **Touplain**: The electrical purification of air.—G. **Gouy**: Gaseous currents in the interior of the sun.—Ch. **Nicolle**, A. **Cuénod**, and G. **Blanc**: The experimental reproduction of trachoma (granular conjunctivitis) in the rabbit.—M. Léon Lindet was elected a member of the section of rural economy in succession to the late Th. Schlœsing, and Sir Joseph Larmor a correspondant for the section of geometry in succession to the late M. Liapounoff.—B. **Gambier**: Applicable surfaces.—Ch. **Rabut**: The group of plane transformations in which all right lines remain right.—A. **Châtelet**:

Abelian bodies of the first degree.—H. **Villat**: The variable movement of an indefinite fluid with streamlines in presence of a solid body.—R. **Thiry**: A problem of hydrodynamics admitting an infinity of solutions.—E. **Belot**: Dichotomic classification of all stars with the hypothesis of their formation by cosmic shock.—Ad. **Braly**: A new, simple, and rapid method for collecting and characterising the sublimates produced by metalloids and metals volatilised by the blowpipe. Two flames are used, alcohol and paraffin, to secure different temperatures of volatilisation, and the sublimates are received on clear mica sheets.—O. **Mengel**: Two ancient lines of beach at Roussillon: their relations with two Glacial periods.—H. **Hubert**: Granitic rocks associated with the diabases of the Doualé massif (Haut-Sénégal and Niger).—J. **Rouch**: The height of sea-waves. The Richard statoscope was used in these measurements; 1 mm. on the scale of the instrument corresponded to about 0·5 metre variation in height. The greatest wave-heights were observed on January 28, 1910, and gave numerous waves between 4 and 5 metres, forty above 6 metres, twenty above 7 metres, nine above 8 metres, five above 9 metres, and one of 10·5 metres. Waves of a greater height than 10 metres are rare in the Atlantic and the southern seas.—P. **Bugnon**: The origin of the transverse liberoligneous bundles forming a network at the nodes of the Gramineæ.—F. **Morvillez**: The liberoligneous apparatus of the leaves of Betulaceæ, Corylaceæ, and Castaneaceæ.—L. **Blaringhem**: The production by traumatism of a new form of maize, *Zea Mays*, var. *polysperma*.—J. **Barlot**: The determination of poisonous varieties of Amanita by colour reactions. The colour reactions of numerous fungi with sulphuric acid and potash solution are detailed. Three very poisonous varieties give a positive "hæmo-reaction" with a mixture of fresh blood and potassium ferricyanide.—R. **Cambier**: The purification of sewage by activated sludge.

Diary of Societies.

THURSDAY, APRIL 15.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—S. Skinner: Ebullition and Evaporation.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir George C. Buchanan: The Ports of India: Their Administration and Development.

LINNEAN SOCIETY, at 5.—Capt. F. Kingdon Ward: Natural History Exploration on the North-east Frontier of Burma.—R. Paulson: Exhibition of Lantern-slides illustrating Definite Stages in the Sporulation and Gonidia within the Thallus of the Lichen *Evernia prunastri*, Ach.

ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.

INSTITUTION OF MINING AND METALLURGY (Annual General Meeting) (at Geological Society), at 5.30.—F. Merricks: The Mineral Production of the Empire (Presidential Address).

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.—Prof. W. Ripman: Spelling Reform.

INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.—Dr. C. V. Drysdale: Modern Marine Problems (Kelvin Lecture).

OPTICAL SOCIETY (at Imperial College of Science and Technology), at 7.30.—J. Weir French: The Unaided Eye, Part III.—R. R Walls: The Rock Crystal of Brazil.

CHEMICAL SOCIETY, at 8.—I. Masson and R. McCall: The Viscosity of Nitrocellulose in Mixtures of Acetone and Water.—S. S. Bhatnagar: Studies in Emulsion. Part I. A New Method for Determining Inversion.—W. H. Gibson and R. McCall: (1) The Influence of Nitroglycerine on the Viscosity of Solutions of Nitrocellulose in Ether-alcohol. (2) The Viscosity of Solutions of Nitrocellulose in Ether-alcohol.—W. K. Slater: Experiments on the Preparation of Isonitroso-derivatives.—C. S. Salmon: Direct Experimental Determination of the Concentration of Potassium and Sodium Ions in Soap Solutions and Gels.—W. C. McC. Lewis: Studies

in Catalysis. Part XIII. Contact Potentials and Dielectric Capacities of Metals, in relation to the Occlusion of Hydrogen, and Hydrogenation.—C. S. Garnett: Colouring Matters of Red and Blue Fluorspar.—Miss P. V. McKie: Determination of Nitroform by Potassium Permanganate.—J. L. Simonsen: (1) The Constituents of Indian Turpentine from *Pinus longifolia*. Part I. (2) Note on the Constituents of *Morinda citrifolia*. (3) Syntheses with the aid of Monochloromethyl Ether. Part IV. The Condensation of Ethyl Benzyl Sodiomalonate and Monochloromethyl Ether.

FRIDAY, APRIL 16.

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5.30.

CONCRETE INSTITUTE, at 6.—E. Fiander Etchells: Submission of Plans to Local Authorities.

INSTITUTION OF ELECTRICAL ENGINEERS (Students' Meeting) (at Faraday House), at 7.—J. Scott-Taggart: The Vacuum Tube as a Transmitter and Receiver of Continuous Waves.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—J. E. Baty and Others: Discussion on Planing *v.* Milling.

TECHNICAL INSPECTION ASSOCIATION (at Royal Society of Arts), at 7.30.—F. R. Wade: Labour Unrest—Its Causes and its Cure.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section), at 8.30.—Sir Ernest Rutherford: Development of Radiology (Mackenzie Davidson Memorial Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. H. Maxwell Lefroy: The Menace of Man's Dispersal of Insect Pests.

SATURDAY, APRIL 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. W. H. Eccles: The Thermionic Vacuum Tube as Detector, Amplifier, and Generator of Electrical Oscillations.

MONDAY, APRIL 19.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting) (at Chartered Institute of Patent Agents), at 7.—G. H. Ayres: Group *versus* Individual Driving.

ROYAL SOCIETY OF ARTS, at 8.—Dr. W. Rosenhain: Aluminium and its Alloys (Cantor Lecture).

SURVEYORS' INSTITUTION, at 8.—C. B. Fisher: Some Problems connected with Agricultural Policy.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Flight-Commander G. M. Dyott: An Air-Route Reconnaissance from the Pacific to the Amazon.

TUESDAY, APRIL 20.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Major G. W. C. Kaye: Recent Advances in X-ray Work.

ROYAL STATISTICAL SOCIETY, at 5.15.—Dr. T. H. C. Stevenson: The Fertility of various Social Classes in England and Wales from the Middle of the Nineteenth Century to 1911.

INSTITUTION OF CIVIL ENGINEERS, at 5.30.—Sir Dugald Clerk: Fuel Conservation in the United Kingdom (James Forrest Lecture).

INSTITUTION OF PETROLEUM TECHNOLOGISTS (at Royal Society of Arts), at 5.30.—G. F. Robertshaw: Methods of Examination of Lubricating Oils.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Technical Meeting), at 7.—Dr. C. E. K. Mees and A. H. Nietz: The Theory of Development.

ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 8.—J. Darch and Others: Discussion on the Lighting of Churches.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—R. G. Brown: The Races of the Chindwin, Upper Burma.

ROYAL SOCIETY OF MEDICINE (Pathology Section), at 8.30.—Annual General Meeting.

WEDNESDAY, APRIL 21.

ROYAL UNITED SERVICE INSTITUTION, at 3.—Rev. Father B. Vaughan Modern Patriotism.

ROYAL SOCIETY OF ARTS, at 4.30.—Air-Commodore E. Maitland: The Commercial Future of Airships.

ROYAL SOCIETY OF MEDICINE (History of Medicine Section), at 5.—Dr. A. Chaplin: The History of Medical Education at the Universities of Oxford and Cambridge.—Mme. Panayotatou: Baths and Bathing in Ancient Greece.

ROYAL METEOROLOGICAL SOCIETY, at 5.—Royal Observatory, Greenwich: Polar Night-Sky Recorder.—Lieut. N. L. Silvester: Local Weather Conditions at Mullion, Cornwall.—J. E. Clark: The Surrey Hailstorm of July 16, 1918.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—J. W. D. Robinson: The Devonian of Ferques (Bas-Boulonnais).—E. S. Cobbold: The Cambrian Horizons of Comley (Shropshire) and their Brachiopoda, Pteropoda, Gasteropoda, etc.

ROYAL MICROSCOPICAL SOCIETY, in conjunction with the OPTICAL SOCIETY and the FARADAY SOCIETY (at the Royal Microscopical Society), 7 to 10.—General Discussion on The Mechanical Design and Optics of the Microscope.—Prof. J. Eyre: Opening Remarks.—J. E. Barnard: A General Survey.—A. *The Mechanical Design of the Microscope.* (*a*) General. Prof. F. J. Cheshire: The Mechanical Design of Microscopes.—C. Beck: The Standard Microscope.—F. W. Watson Baker: Progress in Microscopy from a Manufacturer's Point of View.—P. Swift: A New Microscope.—(*b*) Metallurgical. Dr. W. Rosenhain: The Metallurgical Microscope.—Prof. C. H. Desch: The Construction and Design of Metallurgical Microscopes.—E. F. Law: The Microscope in Metallurgical Research.—H. M. Sayers: Illumination in Micro-metallography.—(*c*) Petrological. Dr. J. W. Evans: The Requirements of a Petrological Microscope.—B. *The Optics of the Microscope.* Prof. A. E. Conrady: Microscopical Optics.—Dr. H. Hartridge: An Accurate Method of Objective Testing.—H. S. Ryland: The Manufacture and Testing of Microscope Objectives.—F. Twyman: Interferometric Methods.

THURSDAY, APRIL 22.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—S. Skinner: The Tensile Strength of Liquids.

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—Prof. W. E. Dalby: Researches on the Elastic Properties and the Plastic Extension of Metals.—H. W. Hilliar: Experiments on the Pressure Wave thrown out by Submarine Explosions.—E. F. Armstrong and T. P. Hilditch: A Study of the Catalytic Action at Solid Surfaces. III. The Hydrogenation of Acetaldehyde and the Dehydrogenation of Ethyl Alcohol in the Presence of Finely Divided Metals. IV. The Interaction of Carbon Monoxide and Steam as conditioned by Iron Oxide and by Copper.—Dr. T. R. Merton: The Structure of the Balmer Series of Hydrogen Lines.—Prof. H. A. Wilson: Diamagnetism due to Free Electrons.

FRIDAY, APRIL 23.

PHYSICAL SOCIETY, at 5.—M. C. E. Guillaume: The Anomaly of the Nickel-Iron Alloys: Its Causes and its Applications (Guthrie Lecture).

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—The late W. J. Lineham: (1) The Hardening of Screw-Gauges with the least Distortion in Pitch (referring to Water Hardening). (2) The Hardening of Screw-Gauges with the least Distortion in Pitch (referring to Oil Hardening).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir Israel Gollancz: Shakespeare's Shylock and Scott's Isaac of York.

SATURDAY, APRIL 24.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. W. H. Eccles: The Thermionic Vacuum Tube as Detector, Amplifier, and Generator of Electrical Oscillations.

[APRIL 22, 1920.

The Promotion of Medical Research.

IT is evident from the correspondence evoked by the leading article in NATURE of February 19 that many scientific workers are keenly interested in the subject of the organisation of scientific research and watch with some apprehension the efforts made to bring original investigators within an official system. Francis Bacon supposed that all scientific investigation must proceed from the general to the particular according to a prescribed set of rules, and gave in his "New Atlantis" "a modell or description of a college, instituted for the interpreting of Nature, and the producing of great and marvellous works for the benefit of man." As every student of the history of science knows, Bacon's method, and all other assumedly infallible systems for creating knowledge, fail to furnish a formula for scientific discovery. New truths present themselves in unexpected places, and the seeker after them has to follow whatever paths seem to be the most promising. Knowing that this is so, and cherishing the freedom of action of true explorers, men of science view with suspicion any schemes for systematising research which may deprive them of their birthright. They do not, however, form a single corporate body concerned solely with the promotion of discovery by the encouragement of genius; wherefore they are rarely considered when research systems are planned by the Bacons of our day.

It was pointed out by Prof. Soddy in NATURE of February 26 that the position is different in medical science, because in this case the profession is able to exact due and proper respect for its members, and to insist, therefore, upon administrative and other conditions which they consider best suited to their needs or to solve the problems with which they are concerned. The recent incorporation of the Medical Research Committee as the Medical Research Council is a very notable event in this connection. After its seven years' work under the National Health Insurance Department, the Committee has been transferred to its new position as the Medical Research Council, under the direction of a small Committee of the Privy Council consisting of the Lord President, the Minister of Health (England and Wales), the Secretary for Scotland, and the Chief Secretary for Ireland for the time being. The Council has been incorporated with a perpetual succession by Royal charter, with powers to hold and use not only moneys and land derived from Parliament, but also property or trusts vested in it by private persons or bodies. It is not merely an Advisory Council, but is in charge of its own executive. These main features sufficiently mark the interest and importance of the new step now taken towards solving that difficult problem in the art of government—the preservation of the freedom and self-government of scientific research work as to both initiative and execution, with due regard to a just responsibility to Parliament in respect of State endowment.

The appointment of the Development Commission in 1911 marked the first modern step towards a solution of this problem of the State endowment of research. For the first time an organisation independent of the administrative Departments was set up to initiate and direct scientific research work in particular directions. The constitutional position of the Commission was anomalous, its functions were too various in kind, and the *personnel* selected for it suffered in quality, perhaps, because it depended too much upon the representative principle. But the work of the Commission, especially in relation to agricultural research, was in charge from the first of scientific men, and in effect, if not in form, the Commission had executive as well as advisory powers.

The next landmark in this development was the formation of the Medical Research Committee in 1913 in connection with the National Health Insurance Department. This was attached directly to an administrative Department, but it was given a singularly free constitution. The Committee was composed of scientific men appointed for their quality as counsellors without subservience to any representative principle; it was empowered to appoint and dismiss its own servants, and it had full executive authority within the widest limits of research schemes of its own initiation when these had received general Ministerial approval.

The outbreak of war brought home to the Government the grave national need for a wider and more liberal State endowment of research. In 1915 a scheme for public expenditure upon scientific and industrial research was developed under the Board of Education, where Dr. Addison was then Parliamentary Secretary. It was natural that this should be modelled in its early stages upon the system of the Medical Research Committee, of the working of which there had already been two years of useful experience; but the new organisation soon departed from that model in some essential points. It was early and

rightly transferred to the Privy Council, where it had independence from any one administrative Department, and could serve all Departments alike. But the council of scientific men became a purely advisory body, as it now is, and the Committee of Privy Council under which the work was to be done was not purely Ministerial and formal, but received the addition of other personally appointed lay members in a position constitutionally superior to that of the scientific members of the Advisory Council. A strong staff of lay officers was progressively appointed upon the executive side as a Department under the Privy Council Committee, not under the direct control of the scientific members of the Advisory Council, and neither appointed nor removable by them.

When the Ministry of Health for England and Wales was constituted in 1919, with corresponding Boards of Health in Scotland and Ireland, the disbanding of the four National Health Insurance Commissions made a new constitution necessary for the Medical Research Committee, the work of which in science has no national boundaries. It could not properly be attached to the Ministry of Health, because, altogether apart from the general arguments against placing a system of free research work under a strong administrative Department, a Committee serving the whole of the United Kingdom could not fittingly be attached to a Ministry responsible only for England and Wales. The obviously right course was to bring the medical research service under the Privy Council, the range of which not only covers the United Kingdom, but also allows easy constitutional relationship with systems of research work throughout the Empire. The problem was to bring the Medical Research Committee into close relationship with the scientific and industrial research system already under Privy Council direction, and equally with other systems that may hereafter be placed there, so as to allow the greatest possibility of co-operation along the innumerable boundary lines of scientific work; at the same time it was necessary to do this without sacrificing any of the freedom which the Committee had already enjoyed in its first constitution, or had worked out in experience and established in its traditions.

The solution of this was given when the new Committee of Privy Council for the work of the Committee—now the Medical Research Council—was established by Order in Council on March 11 last. This Committee provides the formal Ministerial responsibility for moneys provided by Parliament, and at the same time it represents and brings together the interests of all the four parts of the Kingdom. In the absence of the Lord President, the Minister of Health will act as Vice-President of the Committee. The Secretary appointed by the Medical Research Council for its own scientific and administrative purposes is to be *ipso facto* Secretary of this Privy Council Committee, so that the chief executive officer of the Research Council will have direct access to the Minister in charge, without the intervention of lay officials either now or in the future.

The Medical Research Council itself has been incorporated by Royal charter in perpetual succession with legal powers to hold money or other personal property, whether voted by Parliament or derived from other sources, and to accept trusts for the furtherance of medical research. It has licence to purchase and hold land or to receive it by gift or bequest up to an annual value of 50,000*l.*, determined at the time of acquisition.

The personal constitution of the Medical Research Committee upon becoming the new Council is little changed. At least two of its members must always be Members of Parliament, one each in the House of Lords and the House of Commons. Lord Astor and Dr. Addison, holding office in the Ministry of Health, retired from the Committee before the change was effected, and one additional scientific member was appointed, to bring the total number from nine to ten. The constitution of the final Medical Research Committee and of the new Medical Research Council is as follows:—The Viscount Goschen; Mr. William Graham, M.P.; the Hon. Edward Wood, M.P.; C. J. Bond, C.M.G., F.R.C.S.; Prof. W. Bulloch, F.R.S.; Dr. T. R. Elliott, F.R.S.; Dr. Henry Head, F.R.S.; Prof. F. Gowland Hopkins, F.R.S.; Major-Gen. Sir William Leishman, K.C.M.G., F.R.S.; and Prof. D. Noël Paton, F.R.S.

It is laid down that three of these members shall retire on September 30, 1921, and thereafter three at intervals of two years. Vacancies so caused or arising casually are to be filled by appointment by the Committee of Privy Council, but only after consultation with the President for the time being of the Royal Society and with the Medical Research Council. This provision will bring into effective bearing upon the constitution of the

Council the best scientific opinion of the time through the channel of the Royal Society, which is likely to be all the more effective because it is not a formal nomination to be made by a busy Royal Society Council among other business, and it gives direct access by the President to the responsible Ministers. A further important provision is that the charter itself may receive amendment or addition, if majority votes of the Council under stated conditions be obtained and the change be allowed by the Committee of Privy Council.

We have continually urged in these columns that scientific men themselves should decide upon the allocation of funds for research, as is done by the Royal Society, the British Association, and other bodies; and that they should be responsible for any schemes of organised investigation. Friction and misunderstanding always arise when these functions are performed by official administrators unfamiliar with such a sensitive plant as scientific genius and unable to judge the promise of incipient inquiry. The remedy for such difficulties is always to ensure that the men who do the work are the masters of the administrative machine and have confidence in the direction of it by specially qualified colleagues—to promote, in fact, the same spirit of common interest between director and worker that is desired between capital and labour. The Medical Research Council seems to fulfil these conditions in every respect, and its incorporation marks a noteworthy stage in scientific development. The Council can determine its own policy, has complete control of its funds, is in direct touch with progressive science by association with the Royal Society, and, above all, its Secretary, Sir Walter Fletcher, has the full confidence of medical research workers. He knows well enough the truth of the adage, *Poeta nascitur, non fit* as applied to scientific genius, and may therefore be trusted to secure the most favourable conditions for the development of this rare fruit when it appears.

During its existence the Medical Research Committee brought together a brotherhood of research workers whose scientific investigations have been of the highest national value, and it did this without limiting the freedom of action which is their heritage. We confidently look to the new Council to encourage the independent investigator as well as to create a reserve of research workers, and thus consolidate the organisation of scientific effort in the service of medicine so well begun by the Committee which it supersedes.

A Study in Palæogeography.

The Environment of Vertebrate Life in the Late Paleozoic in North America: A Paleogeographic Study. By Prof. E. C. Case. (Publication No. 283.) Pp. vi+273. (Washington: Carnegie Institution of Washington, 1919.) Price 3 dollars.

THE following passage from Suess's "Face of the Earth" might be taken as an appropriate text for the work under consideration:—"It is the organic remains, no doubt, which afford us our first and most important aid in the elucidation of the past. But the goal of investigation must still remain the recognition of those great physical changes in comparison with which the changes in the organic world only appear as phenomena of the second order, as simple consequences." Prof. Case's volume may be described as an attempt both to provide an up-to-date corpus of material, often presented in the form of lengthy quotations from the writings of American geologists, bearing upon the history of the later Palæozoic period, and to utilise the data as evidence in an inquiry into the physical and climatic conditions under which organisms lived, migrated, or became extinct in different regions of the North American continent.

The author has essayed a difficult but attractive task, and though his own conclusions and generalisations are to some extent overwhelmed by the superabundance of citations from published sources, he has succeeded in making a valuable contribution to a neglected branch of geological history. He takes a broad view of the conception of environment; it represents "the sum of all the contacts which any organism or group of organisms establishes with the forces and matter of its surroundings, either organic or inorganic." The difficulty is that we have comparatively little knowledge of the nature of the interaction of existing organisms and their environment; but it is none the less praiseworthy to extend ecological inquiry to a remote era in the hope that in this line of research, as in others, a knowledge of the past may help us to solve the problems of the present.

In the first chapter Prof. Case discusses the different categories of facts which it is essential to consider in connection with palæogeographical questions, the nature of the sedimentary deposits, the source of the sediments, the history of the flora and fauna—whether they were evolved where they were preserved, or had migrated from another locality—the influence of environment reflected in the morphological characters of animals and plants, and other factors. He empha-

sises the importance of close co-operation between palæontologists and geologists in all matters relating to past geographies, and deprecates the over-readiness of the former class of workers to assume the existence of land-barriers. In illustration he refers to the continent of Gondwanaland, the existence of which "depends more definitely upon biological evidence and awaits full confirmation." Gondwanaland is, however, by no means the creation of palæontologists alone; its foundations are also geological. Succeeding chapters are devoted to the description of different provinces of North America in the latter part of the Palæozoic era, and the author summarises the results of an intensive study of Upper Pennsylvanian and Permo-Carboniferous rocks in certain areas. It is difficult for a reader not conversant with American stratigraphy to interpret the formations mentioned in terms of European classification, and one feels the lack of more helpful correlation-tables than those provided.

One of the most valuable features of the book is the emphasis laid on the necessity for regarding fossils as once living things, and for considering their distribution in the strata in relation to the problems presented to them by their environment. The chapter on the climatology of the later Palæozoic is a particularly useful mine of information. In the concluding chapter the author discusses the development and fate of vertebrate life in the Permo-Carboniferous period in relation to physical conditions. During Early Pennsylvanian time the conditions were singularly uniform over large areas, and the climate was equable and humid; a monotonous environment implies a limit to the number of genera and species in a flora or fauna; older and simpler types would persist because the variants, which were possibly being constantly produced, would not have a chance to develop. This idea is elaborated, though not so clearly as one could wish. It is suggested that the Upper Pennsylvanian fauna, though hampered in its further progress by the monotony of the environment, was accumulating force preparatory to a great radiation which would find expression when the limitations were removed. Prof. Case adds: "The fauna, long restrained from any expression of its evolutionary tendencies, full fed, and in the vigour of its youth, responded at once to the change, and new forms appeared so suddenly as to be unheralded in the preserved remains." This and similar passages illustrate the more imaginative side of the author's work.

The palæobotanical data are largely taken from the contributions of Mr. David White, whose researches are well known. The American Coal Measures have unfortunately yielded scarcely any petrified material comparable with that from England and a few other European countries, and although there is a wealth of plant impressions, anatomical criteria of climatic conditions are not available.

A. C. SEWARD.

Wheat and Wheat-growing.

Essays on Wheat. By Prof. A. H. R. Buller. Pp. xv+339. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1919.) Price 2.50 dollars.

PROF. BULLER'S "Essays on Wheat" are among the most interesting things we have seen for a long time. As professor of botany in the University of Manitoba, he has unrivalled opportunities of studying the ramifications of the wheat industry, for in no city in the world is wheat so important as in Winnipeg. He is singularly fortunate in his subject, and he tells his story remarkably well, giving the wealth of detail, the figures, and the references needed by the man of science, without sacrificing interest or literary form.

The first essay deals with the early history of wheat growing in Manitoba. It is a story in which Parkman would have revelled. The first attempt was made in 1812 by a little band of pioneers sent out from Scotland by Lord Selkirk to colonise the 116,000 sq. miles of territory granted to him by the Hudson Bay Co.; they settled at the junction of the Red and Assiniboine rivers where Winnipeg now stands. The first crop failed, as also did the second. The failure is scarcely surprising. "There was not a plow in the whole colony, the one harrow was incomplete and could not be used, and all the labour of breaking up and working over the tough sod had to be done with the hoe." The Indians were amazed, and nicknamed the colonists "jardiniers." Fortunately for the settlers, potatoes and turnips did well, or they must have had two very bitter winters. The third crop succeeded. But the troubles were by no means at an end. Birds were a great nuisance, especially the now extinct passenger pigeon. In the fourth year the adherents of the North-West Company and their half-breeds made serious trouble and caused no little bloodshed, and, to crown all, in the sixth year, just as the settlers were about to reap their second good harvest, there came a great plague of locusts which stripped the fields and gardens bare. It was more than even these brave men could stand; the old record says: "The unfortunate emigrants, looking up to heaven, wept." It speaks volumes for their good Scottish upbringing if they did no

more. Troubles continued; mice and floods did great damage, and not until 1830 did prosperity come; from that time on, however, the tale is one of steady and increasing progress.

Space does not allow of quotations from Prof. Buller's description of modern wheat growing in western Canada, but this is less necessary since it is more generally known than the earlier history. While it has less human interest, the tale is still a fascinating record of what can be achieved by intelligent organisation.

Another essay is devoted to the Red Fife and Marquis wheats. Red Fife was introduced into Canada some sixty years ago, and by reason of its sterling merit and great suitability to Canadian conditions it spread far and wide, doing much to make Canada's reputation as a wheat-producing country. The farmer is rarely a writer, and David Fife, who raised the first crop about the year 1842, has himself left no record of how he did it. But, though written contemporary records are lacking, oral traditions are abundant; some of them are reproduced by Prof. Buller, and they can almost be graded in point of time by their respective wealth of picturesque detail. The earliest written record is in the *Canadian Agriculturist* for March, 1861. It is there related that David Fife, of Otonabee, Ontario, in 1842 procured from a friend in Glasgow a quantity of wheat drawn from a cargo coming direct from Danzig. The wheat arrived in spring and some of it was sown forthwith; it failed to ripen, excepting only three heads, which apparently sprang from a single grain. These were preserved and the grain sown the next year; the progeny did very well, escaping rust, while all round the local wheat was badly infested. Again the grain was harvested separately, and gradually a large stock was worked up and distributed among other farmers.

The Continental origin of Red Fife was definitely established by Dr. Charles Saunders in 1904, when he proved its complete identity with a Galician spring wheat.

Dr. William Saunders, the revered first organiser of the experimental stations in Canada, whose courtly bearing and distinguished kindliness will always be remembered by those who knew him, began soon after 1886 to make crosses between Red Fife and other varieties with a view to improvement. One of the crosses actually made by his son Arthur in 1892 was between Red Fife as male and an early ripening Indian wheat, Hard Red Calcutta, as female. Unfortunately, the Indian wheat is a mixture, and the precise variety used cannot now be determined. When Dr. Saunders's second son Charles became Dominion Cerealist, he made a careful examination of the progeny of this cross, and selected from the mass of material one strain of outstanding excellence, which he called "Marquis," and which, from a single head in 1903, has spread over Canada and the United States, until in 1918 it was sown on 20,000,000 acres of land and yielded some 300,000,000 bushels of grain. So wonderful a rate of growth can scarcely have occurred before in the whole history of the world.

It is not often that a reviewer wishes a book had been longer, but that is decidedly one's feeling in closing this volume. One can only hope that Prof. Buller will find time to give us more of these delightful essays.

E. J. RUSSELL.

The Fertilisation of the Ovum.

Problems of Fertilization. By Prof. Frank Rattray Lillie. (The University of Chicago Science Series.) Pp. xii+278. (Chicago, Ill.: The University of Chicago Press; London: The Cambridge University Press, 1919.) Price 1.75 dollars net.

THE problem of fertilisation, of what really happens when the spermatozoon meets the ovum, and of how the latter is incited to begin the long series of rhythmical cleavages that finally result in a new organism, is one of the most interesting and at the same time one of the most complex in biological science. From the time of Aristotle, who held that "the female always supplies the matter, the male the power of creation," the problem has engaged the attention of biological philosophers, and no doubt it will continue to do so for generations to come, for the more it is investigated the more intricate it becomes, and each new theory, evolved under the influence of new experimental methods, is discarded in turn as our knowledge of facts increases. Not the least interesting part of Prof. Lillie's book is the historical survey with which it opens. The discovery of the spermatozoon by Leeuwenhoek and Hamm in 1677 was epoch-making for biological science, and, of course, was rendered possible only by the advent of the compound microscope. Like all other great discoveries, it was immediately followed by sensational nonsense, and we find "a certain Dr. Dalen Patius" claiming that the human body is actually visible in perfect miniature within the spermatozoon! This grotesque view, however, was but an extreme form of that held by the spermatist school in general, which maintained that the ovum plays no other part in the production of the young animal than that of furnishing the germ contained in the spermatozoon with nourishment.

The elaboration of microscopical technique in the nineteenth century, leading to the discovery of the cell, with its nucleus and chromosomes, afforded conclusive evidence that ovum and spermatozoon contribute more or less equally to the organisation of the new individual, and placed upon a secure foundation the fundamental generalisation that both are cell-units. Exactly how they co-operate in initiating development is the problem discussed by Prof. Lillie, in the light both of his own observations and of those of a small army of fellow-workers in the same field, pre-eminent amongst whom stand out the names of Hertwig, Fol, Boveri, Delage, Loeb, and E. B. Wilson.

There is one fact of fundamental importance about which all observers seem now to be agreed, and that is the twofold character of the process of normal fertilisation; not only does it stimulate the egg to develop, it also results in the combination of maternal and paternal chromosomes in the zygote nucleus. This combination is of the most far-reaching significance for the theory of heredity, but it appears to have little or nothing to do with the "activation" of the ovum which leads to development, and is only incidentally referred to in the volume before us.

As to how the activation is effected, there seem to be almost as many views as there are observers. It is well known, however, that activation can take place without the aid of a spermatozoon, and that artificial parthenogenesis may be brought about by a great variety of methods, involving the application of chemical or physical stimuli. The problem is one of physiological chemistry, and apparently many factors may be concerned in the process. The secretion of a substance by the egg which causes the spermatozoa to agglutinate and adhere to the surface, appears to be one of the most important. The formation of the so-called "fertilisation-membrane" as a result of the impact of the spermatozoon and the consequent cortical changes that take place in the ovum are fully discussed, and the hypothesis is put forward that a substance ("fertilizin") exists in the cortex which exerts a ferment-like action as it penetrates into the egg, or is carried in by the spermatozoon, and it is suggested that the spermatozoon itself requires to be "fertilised" by passing through the cortex before it can play its proper part in the events which take place internally and lead to development.

The book contains a vast amount of information as to recent discoveries and theories, and will serve as a very useful guide to those who wish to follow up this most intricate subject. A. D.

Wisdom of Life and Existence.

A Gentle Cynic: Being a Translation of the Book of Koheleth, commonly known as Ecclesiastes, stripped of Later Additions; also its Origin, Growth, and Interpretation. By Prof. Morris Jastrow, jun. Pp. 255. (Philadelphia and London: J. B. Lippincott Co., 1919.) Price 9s. net.

PROF. MORRIS JASTROW, jun., of the University of Pennsylvania, is well known among scholars as one of the best equipped analysts and interpreters of Biblical lore. In this volume he has taken the Book of Koheleth in its origin, growth, and interpretation, and thrown a good deal of fresh light on the subject.

In a foreword of twenty pages is given a very able sketch of the main principles of Biblical criticism and of the enormous gain which accrues from a knowledge and acceptation of them. By such means only are we able to pass from the realm of confusion to that of clearness. In our generation alone has the religious portion of mankind come to realise this necessity, and even to-day the realisation is but a portion of a small minority. Yet only by the adoption of scientific methods can the past be illumined in the realm of religion, as it has been illumined in every other field.

The author passes on to examine the origin and structure of the Book of Koheleth. Here he arrives at the conclusion that the book, as we possess it to-day, is an expanded and edited rendering of an earlier version, which, when it is viewed without the accretions, presents a gentle criticism of human life and existence. The version knows nothing of what lies behind or before us. It really deals with man's passage through life, and emphasises the present infinitely more than either the past or the future. Man is asked to make the most of the good things that Nature brings to him; he is warned not to worry about speculative things, such as his own final goal or the destiny of the universe. In spite of much that is hidden, life has a meaning here and now; it has enjoyments which make it worth while to live.

Now, it is evident that such an empirical, Epicurean view of life would never do as a *religious* interpretation of the universe or of life itself. As it stood originally, the Book of Koheleth had no chance of entering into the sacred books. It is therefore edited, added to, and polished so as to furnish here and there pious injunctions of rewards and punishments in order that the life

of the present may be lived in accordance with "ideal ends." God and the future are brought in as the norms to which life has to conform.

This portion of the book is a brilliant piece of work, and the author has brought to bear upon it not only great learning, but also a lightness of touch which really borders on something like originality. In the hands of men such as Prof. Jastrow, the Bible can again become a work of immense significance.

The next part of the book presents us with the words of Koheleth in their original form, stripped of later interpolations, sayings, and comments. The translation of Koheleth is excellent, and in reading it we seem to be brought face to face with a book published yesterday, because it looks upon the world of Nature and of life from a point of view which cannot be neglected. Of course, such aspects do not exclude others, but it is always well to make the best use of each point of view, and not to try to form a composite so vague that no meaning can be extracted from it. No doubt Prof. Jastrow had something like this in mind when he undertook the preparation of this volume, and we sincerely hope he will deal with other composite books of the Old Testament as he has done so splendidly with the Book of Koheleth.

New Books on Industrial Chemistry.

(1) *Applied Chemistry: A Practical Handbook for Students of Household Science and Public Health.* By Dr. C. Kenneth Tinkler and Helen Masters. Vol. i., *Water, Detergents, Textiles, Fuels, etc.* Pp. xii+292. (London: Crosby Lockwood and Son, 1920.) Price 12*s.* 6*d.* net.

(2) *Chemistry from the Industrial Standpoint.* By P. C. L. Thorne. (New Teaching Series.) Pp. xvi+244. (London: Hodder and Stoughton, 1919.) Price 4*s.* 6*d.* net.

(3) *Fuel, Water, and Gas Analysis for Steam Users.* By John B. C. Kershaw. Second edition, revised and enlarged. Pp. xii+201. (London: Constable and Co., Ltd., 1919.) Price 12*s.* 6*d.* net.

(4) *Popular Chemical Dictionary.* By C. T. Kingzett. Pp. vi+368. (London: Baillière, Tindall, and Cox, 1920.) Price 15*s.* net.

(1) THIS work is mainly intended for students in their third year who are preparing for diplomas in household and social science, and for diplomas and degrees in public health of the various universities. There is no work known to the reviewer that covers the ground in the same manner as this. The book is clearly and attractively written, and forms a most useful addition, not only to the academic student, but also to the works chemist, who must often adjudicate upon matters such as are dealt with in this work.

The book does not deal with manufacturing operations, but gives a clear and practical exposition (with the necessary theoretical explanations) of the methods employed in analysing and appraising the value of water, water softening processes, soap, textile fibres, bleaching agents, dry cleaning, air analysis, gaseous fuels, liquid and solid fuels, materials used in the protection of wood, metallic and other surfaces, etc. Although the authors themselves make no claim to originality, many of the subjects are treated in a manner very different from that prevailing in most of the existing works on the subject. Every technical chemist should possess a copy of this work for reference, as there is collected together here in one volume a large mass of material which is usually scattered piecemeal throughout a number of expensive treatises. Altogether this is a book to be thoroughly recommended, and it should command a wide sale.

(2) Mr. Thorne has written an interesting little book on a very large subject, which is clearly and attractively explained, and the volume marks a considerable departure from the older style of text-book. Not very long ago a book of this type would have enjoyed no sale, but would have been coldly received in scientific circles, and the advent of such a work shows what a revolution has been wrought in the chemical world within the last few years. The reviewer cannot help thinking, however, that Dr. Briscoe's excellent introduction is somewhat hard upon the business man. His own experience is that the business world is very much alive to scientific possibilities, whereas the purely professional university-trained chemist of the past was not only largely unpractical, but also held himself aloof from the problems of the business man, and the latter's caution was founded in many cases upon heavy losses attained by contact with the semi-scientific "expert," who regards the business man as his natural prey.

For the earnest technical student or the trained works chemist the book naturally is not of great use, as it cannot go into exact detail. For a young chemist, however, entering works for the first time, it gives an excellent summary of the main operations involved in chemical industry, and is well up-to-date as regards modern develop-

ments, as witness the references to rotary filters, catalytic action, hydrogenation of fats, etc.

The ordinary business man engaged in dealing with the products of chemical industry will undoubtedly derive considerable benefit from the perusal of this volume. The style is clear enough to be intelligible even to the non-technical reader.

(3) Fuel and water are such important subjects industrially that any book dealing with them is bound to receive serious attention from every works chemist and steam user. The present work (now in its second edition) meets a well-defined want in that it gives trustworthy and up-to-date technical methods of analysing fuel, water, and gas.

Part i. deals with fuel, fuel sampling, analysis of fuel, thermal values of fuel, etc., and is excellent. Part ii. deals with water as applied to technical purposes; methods of sampling and analysing it, of softening, and of calculating the amount of softening materials to be added, are given in full. Here, in a concise form, are the materials upon which a practical opinion can be formed as to the best methods of dealing with any given type of water. The subject of part iii. is waste gases, their sampling, analysis, and valuation.

The work is written by an authority who is in practical touch with the numerous and difficult problems relating to fuel and water which every works chemist has to handle. It can be recommended to every industrial chemist.

(4) The author has achieved his aim of producing a "popular" dictionary of chemistry, and the work, so far as it goes, is very complete, almost every well-known chemical or piece of chemical apparatus being briefly mentioned. It is very difficult to see, however, for what class of reader such a work is intended. For purposes of strict reference, the volume is far too "popular." For example, on looking up the word "pyridine," we are informed that it is "a nitrogenous base present in bone oil, and in tar obtained from shale and coal." No mention is made of its boiling point, specific gravity, constitutional formula, solubilities, etc., which the average reader would require. This is typical of the work. In the reviewer's experience, no one looks up chemical terms for amusement. Definite *quantitative* information is what the user of a dictionary requires in ninety-nine cases out of a hundred, and it is these quantitative data which are so conspicuously lacking in the present volume. The constants of most of the materials should have been given in a work of this kind. G. M.

Our Bookshelf.

The Theory of Heat. By Prof. Thomas Preston. Third edition. Edited by J. Rogerson Cotter. Pp. xix + 840. (Macmillan and Co., Ltd., 1919.) Price 25s. net.

It is pleasant to meet an old friend still going strong in spite of years and changing fashions. In these days of rapid progress a quarter of a century is a long period in the life of a book dealing with a living science. The secret of the continued popularity of Preston's work is no doubt to be found in the fact that the book was written as a labour of love in the interests of true scientific education, instead of being merely compiled to suit an arbitrary standard or syllabus, adapted to a particular type of student, or a special limit of mathematical attainment. The object has been to give a comprehensive survey of the development of the theory of heat from an historical point of view, which possesses many advantages in the exposition of a scientific subject.

The historical order of evolution, both in theory and in experiment, generally follows the natural processes of reasoning of the human mind, and introduces fresh ideas in a regular sequence in which they are readily assimilated. The deductive method, starting with a general law or formula, may frequently provide a more direct means of arriving at any particular result or practical application, but it tends to obscure the essential foundation on experiment, and to rob the subject of human interest. From the point of view of the general reader, as distinguished from the special student, there can be no comparison between the two methods. There is an illusion of finality in the deductive method which appeals to the mathematical mind, but the historical method, when illustrated, as in Preston, by a critical discussion of typical experiments, is the more suggestive, inspiring the student to think for himself and to make further advances.

The book is so well known that it only remains to add that Mr. Cotter has shown himself to be a most sympathetic and capable editor in both pruning and grafting. The important additions, on recent advances in the theory of radiation and specific heat, and on the kinetic theory of gases, are admirable summaries, conceived and carried out in the spirit of the original. H. L. C.

Royal Botanic Gardens, Kew: Bulletin of Miscellaneous Information, 1919. Pp. iv + 459 + 39. (London: H.M.S.O., 1919.) Price 4s. 6d. net.

This volume contains the ten numbers of the *Kew Bulletin* which were published at intervals from April to December, 1919. The thirty-three articles include papers and miscellaneous notes of both economic and strictly botanical interest. Mr. J. H. Holland contributes a useful list of food and fodder plants arranged under their respective families, with notes on their origin, uses, popular names, etc. There are also papers

on "The True Mahoganies," by Mr. R. A. Rolfe, and "The Jerusalem Artichoke," by Mr. C. C. Lacaita; the latter is an exhaustive discussion on the introduction of this vegetable to the Old World and the origin of its popular name. An account is given of Lord Ventry's experiments on growing New Zealand flax in Ireland; the evidence goes far to show that the possibility of growing it in South-West Ireland as a commercial undertaking is an established fact. "Silver-leaf Disease" and "The Skin-spot Disease of Potato-tubers" are the titles of two important contributions on plant-diseases by Messrs J. Bintner and M. Nest Owen respectively. Results of botanical exploration are embodied in Dr. Hemsley's account of the flora of Aldabra and adjacent islands and in Mr. Turrill's *résumé* of the botanical results of Swedish South American and Antarctic expeditions.

The more purely botanical papers include a careful examination, by Sir David Prain and Mr. Burkill, of the identity of the plant, or plants, known under the name *Dioscorea sativa*; and a revision by Mr. W. B. Grove of the species of the fungus genus Phoma. There is also an historical account of the botanic garden of Pamplemousses, Mauritius; and the new flagstaff at Kew and its erection are described in detail. The obituary notices include those of Prof. J. W. H. Trail of Aberdeen and Prof. W. G. Farlow of Harvard.

The Story of Milk. By J. D. Frederiksen. Pp. xx+188. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1919.) Price 9*s.* net.

THE author tells his story in a clear and interesting manner, and the general reader, as well as the student of domestic science or dairying, will follow the contents of the book with pleasure and profit. The subject-matter is sound, and the concise, practical directions will be valuable to anybody who is acquainted with the general methods of butter-making and cheese-making.

There are sections dealing with the composition and properties of milk, the testing of milk, the part played by enzymes and bacteria, and the methods by which organisms are utilised or controlled. Milk supply and butter-making and the manufacture of ice cream are the chief subjects of another section. As the book is written for American readers, the sixteen pages devoted to recipes for ice cream are perhaps not excessive, and they will not fail to raise in the English mind a feeling of envy that such delectable things as parfaits and mousses are not more general.

Cheese-making is well dealt with, and working details are supplied, whilst the methods adopted in the manufacture of condensed milk, milk powder, and casein are briefly sketched.

Very rightly the food value of milk is given a prominent place, and the recipes for dishes in which milk or cheese forms an important part are attractive, and should be found very useful to many. A certain amount of historical information is given, and the names and labours of notable workers in the various branches of dairying are also to be found in the book.

A First Year Physics for Junior Technical Schools. By G. W. Farmer. With an Introduction by S. C. Laws. Pp. x+183. (London: Longmans, Green, and Co., 1920.) Price 4*s.* 6*d.*

THIS book is intended for use by boys of between twelve and fourteen years of age who have just completed the elementary-school course and are passing to a more advanced curriculum such as is provided in the junior technical, central, or continuation school. It may suit the courses in some of these institutions, but if this is to be the only kind of instruction in physics during the first year of study, the diet cannot be said to be too stimulating. The work is concerned almost entirely with the use of simple measuring instruments. The description of three methods of verifying "Pythagoras," of four ways of measuring the weight of a cubic centimetre of water, and of no fewer than eleven experiments to show that air exerts pressure indicates too much devotion to completeness of detail at the expense of time which could be spent more profitably in giving the pupils glimpses at the marvels of Nature by which they are surrounded.

The Struggle in the Air, 1914–18. By Major Charles C. Turner. Pp. viii+288. (London: Edward Arnold, 1919.) Price 15*s.* net.

MAJOR TURNER gives an extremely instructive and readable account of the development of aircraft from 1914 to 1918. With the work of a generation compressed into four years of war, it is not surprising that the developments and events narrated crowd upon each other in bewildering succession. The psychology of flying and the official requirements as regards details of machines for war purposes form exceptionally valuable chapters of the book.

Calculation of Electric Conductors. By William T. Taylor. Pp. 34. (London: Constable and Co., Ltd., 1919.) Price 10*s.* 6*d.* net.

A CHART supplied with the book enables the electrical engineer to determine the size of a conductor required to convey a current of a given value when the voltage drop and length of cable are given, or to find any of these quantities when the three others are given. With the help of the explanatory text all the ordinary cables and systems can be thus dealt with.

Revision Arithmetic, Logarithms, Slide Rule, Mensuration, Specific Gravity, and Density. By Terry Thomas. Second edition, revised. Pp. 62. (London: Crosby Lockwood and Son, 1920.) Price 2*s.* 6*d.*

NUMERICAL examples and answers are given. The standard is that of the Army and Navy Entrance Examinations.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Separation of the Element Chlorine into Normal Chlorine and Meta-Chlorine, and the Positive Electron.

THE very important letter of Dr. Aston in NATURE of December 18, 1919, gives much evidence in favour of a theory of the structure and composition of the nuclei of complex atoms as published by me five years ago and in a number of more recent papers. This theory led me to the idea, as published at that time (Journal of the American Chemical Society, xxxvii., pp. 1367–96, especially pp. 1390, 1391, and 1387), that among the light elements magnesium, silicon, and chlorine, in addition to neon (as found by Thomson), are mixtures of isotopes. The atomic weights of the normal isotopes were given as 24 for magnesium, 28 for silicon, and 35 for chlorine. It was also stated that nickel, copper, zinc, and practically all the other elements between atomic numbers 28 and 80, the latter being mercury, are mixtures of isotopes; while radio-active evidence shows that elements 81 (thallium) to 92 (uranium) exist in isotopic forms. This theory was recently summarised in a paper sent to the *Physical Review* in May and November, 1919. This paper, as well as the others, should be consulted for the details of the theory.

In February, 1916, I announced that we were working in this laboratory upon the separation of chlorine into isotopes by diffusion (*ibid.*, xxxviii., p. 221, 1916). Early in 1917 Mr. W. D. Turner, my research assistant, found slight differences in density between the heavy and light fractions obtained by diffusing chlorine, but, since small amounts of impurities were very difficult to exclude, this did not seem at all conclusive. Since if there are two isotopes of chlorine there are three molecular forms of the substance, a separation may be made more easily by the use of hydrogen chloride gas, and this has been used in nearly all our work for the last three years, though practically nothing was done during the period of the war.

The diffusion of this gas, as carried out on a moderately large scale by Mr. C. E. Broeker and myself, seems now, judging by our preliminary analyses, to be resulting in a definite separation of the gas into a heavier and a lighter fraction. The separation, while extremely slow, seems from our preliminary results on the heavy fraction to be of about the order to be expected by the Rayleigh diffusion theory, provided the atomic weights of the isotopes are 35 and 37; so the work is in good agreement with that of Dr. Aston. These results may be modified somewhat when our precise atomic weight determinations are made, since at the present time all our determinations are made by rapid methods. Our results suggest, but are not of a sufficient precision really to indicate, the possibility that a third isotope of higher atomic weight may exist, but since the separation is extremely slow, and the positive ray method as worked out by Dr. Aston gives results very quickly, he should be able to test this suggestion much more rapidly than ourselves.

Since 1916 we have diffused about 19,000 litres of hydrogen chloride gas as measured under standard conditions. The apparatus now in use will diffuse about 400 litres per day, and we hope soon to raise the capacity to 1000 litres. These numbers refer to the fresh or ordinary gas introduced into the apparatus, and not to that which is rediffused in smaller units. The total number of units now in operation is five, and the method may be described as a fractional diffusion.

While the idea that the hydrogen nucleus may be the positive electron is a very general one, the only evidence I have found in print which gives real support to this idea, and explains the facts which seem opposed to the idea, is to be found in papers by my associates and myself as cited above, and in my other papers listed at the end of this letter. The hydrogen nucleus or the positive electron has, according to these papers, a weight, and presumably a mass, of 1·000, on the basis of oxygen as 16·000, whenever the positive electron is combined in a complex atom. The atomic weight of ordinary hydrogen is 1·0077. The difference between 1·0077 and 1·000 is due either to the existence of meta-hydrogen of atomic weight 3·00 and composition $(\eta_3\beta_2)^+e^-$ in ordinary hydrogen, or else to an electromagnetic packing (possibly to both), the latter as assumed by Sir Ernest Rutherford and by myself, but the details of which are to be found in my papers. In these formulæ η^+ is the positive electron, β^- the negative electron when it is contained in the nucleus, and e^- when it is a non-nuclear or planetary electron.

The nuclei of atoms are built almost entirely from the following particles[1]:—

			Weight (oxygen basis)
Alpha particle or helium nucleus	(α^{++})	$=(\eta_4^+\beta_2^-)^{++}$	4·00
Nu particle or meta-hydrogen nucleus	(ν^+)	$=(\eta_3^+\beta_2^-)^+$	3·00
Mu particle	(μ)	$=(\eta_2^+\beta_2^-)$	2·00

Of these the α particle forms the greater part of all complex atoms; one ν particle is found in most atoms of odd atomic number, at least among the light atoms; and the μ particle, which has no net charge, is responsible for the existence of one of the two known classes of isotopes. The other class of isotopes is due to the presence of the group $\eta_4^+\beta_4^-$, which consists of an α particle, together with two cementing electrons. It is these cementing electrons which are shot off in β disintegrations of radio-atoms, and they always escape in pairs—that is, one directly after the other, or one just before and one just after the escape of an α particle. The number of *negative* electrons in the nucleus of an atom is almost always *even*, whether the nuclear charge is odd or even, but the number of *positive* electrons is nearly always *odd* in a nucleus of *odd charge*. However, the nuclei which contain an even number of positive electrons, and are therefore built up either of α particles alone or of α particles and negative electrons, are, on the whole, much more stable than those with an odd number; so the even-numbered elements are much the more abundant, and make up 98·7 per cent. of the meteorites and the greater part of the material of the earth. Furthermore, all the seven most abundant elements in the meteorites have an even atomic number, as is indicated in Fig. 1.

In the exceptional case of nitrogen the group $\eta_2\beta$ is present, and in beryllium the group $\eta\beta$. A *suggested* structure for the α particle is given in Fig. 2, where the large circles represent negative, and the small ones positive, electrons. The ν group probably has a similar structure, but with three positive electrons at the corners of a triangle; while the lithium nucleus

[1] The negative electrons in these particles may be called *binding* electrons, while those which attach extra α particles are called *cementing* electrons.

is assumed to consist of one α and one ν group, with a symmetrical arrangement of the seven positive electrons. *Two α particles do not seem to combine, but from three to eight, and also ten, α particles combine without the inclusion of any cementing electrons*; but when more than ten unite, two or a

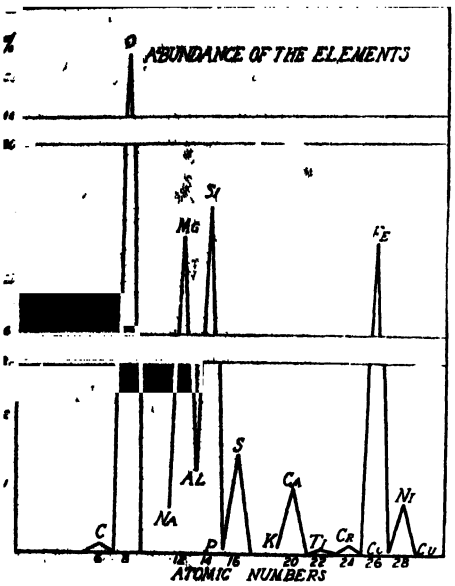

FIG. 1.

multiple of two negative electrons are used in cementing on *extra α* particles—that is, α particles which do not contribute to the positive charge on the nucleus.

Argon and calcium have *isomeric* atoms, the formula

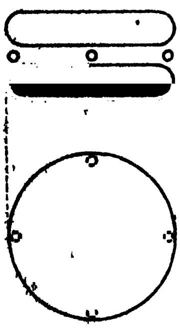

FIG. 2.

of the former being $\alpha_{10}\beta_2 e'_{18}$ and that of the latter $\alpha_{10}e'_{18}e_2$, so both have the general formula $\alpha_{10}e_{20}$. The formulæ given below represent a few characteristic atoms:—

Even Nuclear Charge		Odd Nuclear Charge	
C	$\alpha_3 e'_2 e_4$	N	$\alpha_3\eta_2\beta e'_2 e_5$
O	$\alpha_4 e'_2 e_6$	F	$\alpha_4\nu e'_2 e_7$
S	$\alpha_8 e'_{10} e_6$	Cl	$\alpha_8\nu e'_{10}e_7$ and $\alpha_8\nu\mu e'_{10}e_7$
Fe	$\alpha_{14}\beta_2 e'_{18} e_8$	Co	$\alpha_{14}\nu\beta_2 e'_{18} e_9$
Thorium Series		**Uranium Series**	
Th	$\alpha_{58}\beta_{26}e'_{86}e_4$	U	$\alpha_{59}\mu\beta_{26}e'_{86}e_6$
ThX	$\alpha_{56}\beta_{24}e'_{86}e_2$	Ra	$\alpha_{56}\mu\beta_{24}e'_{86}e_2$
Pb(Th)	$\alpha_{52}\beta_{22}e'_{78}e_4$	Pb(Ra)	$\alpha_{51}\mu\beta_{20}e'_{78}e_4$

Here e represents a valency electron, e' a non-nuclear electron in one of the inner shells, and β a cementing electron in the nucleus. The evidence for these formulæ is good, but cannot be presented here.

It will be seen that this hydrogen-helium-meta-hydrogen theory of atom-building is based upon the atomic weight and atomic number relations; the Rutherford atom; the rule of Soddy, Fajans, and Russell for radio-active changes; and the atomic weight relations discovered by Rydberg about thirty years ago; and is dependent for its validity upon the existence of chlorine, magnesium, silicon, and the heavy atoms in isotopic forms. It is a resurrection and an extension of the hypothesis of Prout.

WILLIAM D. HARKINS.
Department of Chemistry, University of Chicago, March 8.

I HAVE read Prof. Harkins's letter with great interest. If Prof. Harkins has succeeded in separating the isotopic hydrochloric acids he is certainly to be congratulated. The very meagre positive results from my work with neon described at the British Association meeting in 1913 convinced me of the extreme difficulty and labour of such diffusion experiments. In the case of neon I had only to grapple with a twentieth root in the diffusion equation, whereas with HCl it is the thirty-sixth root which is involved. In connection with the possibility of a third isotope of chlorine in the full account of my recent analysis of this element, now in the press, I have described a faint line at 39 which may be this.

More experimental results will be required before the time is ripe for the formulation of a comprehensive theory of atomic structure. I do not propose, therefore, to discuss the one put forward by Prof. Harkins, but would like to point out that his basal assumption that the positive electron has a weight 1·000 is definitely contradicted by experimental results quoted in my letter in NATURE of March 4. F. W. ASTON.

Cavendish Laboratory, Cambridge, April 20.

On Atomic and Molecular Structure.

THE statement of Mr. S. C. Bradford in the second paragraph of his letter to NATURE of April 8, that I suppose the electrons to revolve in small circles *without any constraining force*, is erroneous. The fact that I reserved an opinion as to the nature of the constraining force does not imply, as he suggests, that I deny its existence. Thus (*cf. Science Progress*, April, 1920, and Phil. Trans. Roy. Soc., vol. ccxx., p. 247, 1920) an electron moving with speed v perpendicular to a magnetic field of intensity H (which may originate in the nucleus) describes a circular orbit of radius $\rho = mv/\mathrm{H}e$, and the frequency of the electron is $\nu = \mathrm{H}e/2\pi m$, which (and this is an advantage in the case of a radiating orbit) is independent of the speed with which the electron describes the orbit. At present we know little about the actual value of v. If H is of the order 10^7 gauss, the value ascribed to the molecular field from magnetic considerations, the frequency is that of infra-red radiation, and the correlation of the elastic properties of the medium (which are determined by this molecular field) with the infra-red vibrations, as originally pointed out by Debye, is apparent. Within an atom the controlling field may be of the order 10^8 gauss, which gives rise to vibrations of optical frequency. Closer to the nucleus a field of 10^9 gauss gives rise to frequencies comparable with those of a K series.

Finally, it should be pointed out that the ring electron theory, which Mr. Bradford attributes to

Dr. H. S. Allen, was originally expounded by Mr. A. L. Parson (Smithsonian Miscellaneous Collections, vol. lxv., p. 1, 1915). The advantages of such a theory were ably expressed recently by Dr. Allen in an opening address before the Physical Society of London.

A. E. Oxley.

The British Cotton Industry Research Association, 108 Deansgate, Manchester.

Aquarium Cultures for Biological Teaching.

The increase in the number of students in biology during the last few years has created a demand for large quantities of such animal types as Amœba, Actinosphærium, brown Hydra, and Daphnia. It is often very difficult to obtain to time vast numbers of these types; for in Nature the supply is exceedingly precarious, depending as it does on conditions which are constantly fluctuating. In endeavouring to secure a continuous and plentiful supply of *Amoeba proteus*, I have accumulated a certain amount of experience in aquarium-keeping on a large scale, the results of which will be useful to others who, like myself, have to deal with large numbers of students.

Information with regard to Amœba culture has already been given in "Notes on the Collection and Culture of *Amoeba proteus* for Class Purposes" (Proc. Roy. Phys. Soc. Edin., vol. xx., part 4, p. 179). Since the publication of that note, however, I have tried, as an alternative plan for procuring the material necessary to inoculate a culture, a modification of the respective methods described by J. B. Parker ("A Method of Obtaining a Supply of Protozoa," *Science*, N.S., vol. xlii., No. 1090, p. 727, 1915), Libbie Hyman (*Journ. Exp. Zool.*, vol. xxiv., No. 1), and Asa A. Shaeffer (*ibid.*, vol. xx., No. 4), and with success.

Water from such places as the drainage-cuttings in birch, alder, and willow woods, or from the margins of ordinary pools and ponds, together with the filamentous algæ and the brown scum and included diatoms overlying the dead leaves and the other decaying organic matter forming the floor of such places, is gathered in autumn or in early spring. This is allowed to stand in tap-water for some time, until a rich brown scum appears on the top. The top water with the scum is poured off into another glass vessel, and wheat is added (1 gram to a litre of water). In February minute Amœbæ begin to make their appearance; these become fully grown in May and June, and will then divide rapidly, forming a luxuriant culture until the late autumn, when encystment of most individuals again takes place.

Once started, Amœba cultures require no further attention than a supply of water to compensate for evaporation, and the addition of wheat from time to time.

I am indebted to Prof. Bourne, of Oxford, for information that boiled rain-water can be used in those districts, *e.g.* Oxford, where the tap-water contains much mineral matter.

Actinosphaerium.—My principal difficulty in the culture of Actinosphæria has been in maintaining for them a sufficient food-supply. Stentors and vorticelloids, their favourite food, appear to require running water, and therefore quickly die off when introduced into the laboratory (except the green stentor, which thrives well when once established, and a small vorticelloid which appears in infusions of certain pond-weeds). The common rotifer is an excellent food, and this can be obtained from rubbish left over from pond-gatherings by means of wheat or hay infusion. Members of the family Cathypnadæ (especially Monostyla, which is of frequent occurrence in Amœba cultures, and therefore easily grown in wheat-water) are the most useful of the above-mentioned foods.

Since Actinosphæria disappear very quickly when their food is exhausted, and since, on the other hand, they grow and multiply very rapidly when the food-supply is good, and very quickly exhaust this food-supply, it is necessary to give the Rotifer culture a good start before introducing the Actinosphæria into it. In practice I have several Monostyla cultures in readiness, and then, about three months before requiring large numbers of Actinosphæria, I inoculate one or more of the Monostyla cultures with a few Actinosphæria and set the jar aside. These latter soon multiply and appear in myriads.

Hydra.—Large brown Hydra showing buds and reproductive organs can be obtained in considerable numbers and very quickly in laboratory cultures (especially in rooms with a fairly uniform temperature of 60° F.) if they are systematically fed on a generous diet of Crustaceans, which latter can be obtained by the culture of Daphnia. The Daphnia should be strained off by means of a small net, and a concentrated mass of them in a small quantity of water should be added periodically to the jar containing the Hydra. Several hundreds of Hydra by this means can be obtained from one or two individuals in a few weeks.

Interesting colour-changes, varying from dingy brown to a bright pink, can easily be effected in brown Hydra by varying the Crustacean diet.

Daphnia.—I am indebted to Mr. P. Jamieson for the discovery of the value of small pieces of earthworm for the cultivation of Daphnia. If an infusion of dead earthworms in water be allowed to stand in a warm place (*i.e.* near the radiators in the laboratory) it is quickly converted into a rich food, which can be added to the Daphnia cultures as required. A few Daphnia introduced into a large wide-mouthed glass bottle or beaker of water, to which the worm-water is regularly added, very quickly multiply. Several of these cultures should be kept going if the cultivation of Hydra is very intensive, as they must be allowed to recuperate after they have been depleted by use.

A variety of other Protozoa, Crustaceans, Oligochætes, etc., make their appearance in the above-mentioned cultures, commonly sufficient to supply abundant material for demonstration purposes.

Ionisation in the Solar Chromosphere.

It is well known that the spectrum of the upper layers of the solar chromosphere is chiefly composed of those lines which are relatively more strengthened in the spark than in the arc, and which Sir Norman Lockyer originally styled enhanced lines. The best-known examples are the calcium H and K and the strontium pair (4216, 4077). According to modern theories of spectral emission, these lines are due to an atom which has lost one electron. The principal line due to the normal atom of calcium is the *g*-line 4227, and the corresponding Sr line is 4607, both of which occur at much lower levels. According to modern theories, therefore, Ca, Sr, and Ba atoms are more and more ionised as we approach the upper layers of the solar atmosphere, while in the lower layers both normal and ionised atoms occur.

If we assume that ionisation is a sort of reversible chemical process taking place according to the scheme $Ca \rightleftharpoons Ca^{+} + e - U$, where e is the electron, Ca^{+} is a positively charged Ca atom, and U is the energy of

ionisation, we can apply Nernst's theorem of the "reaction-isobar" to calculate the amount of ionisation under any given thermal stimulus. The method is based upon a remark of Nernst in his book, "Der Neue Wärmesatz . . ." (p. 154), that the electron may be regarded as a monatomic gas of molecular weight $\frac{1}{1838}$, and that its chemical constant can be calculated according to the Tetrode-Sackur relation

$$C=\log\frac{(2\pi m)^{\frac{3}{2}}k^{\frac{5}{2}}}{h^3}.$$

It has recently been applied by Eggert (*Ver. d. D. Phys. Gesell.*, December 15, 1919) for the calculation of the degree of ionic dissociation in the interior of a star, as supposed by Eddington in his theory of stellar structures. But Eggert calculates U in a rather artificial manner for iron from assumed atomic dimensions and structures of the iron atom.

We can, however, calculate U directly from the value of the ionisation potential as experimentally determined by Franck and Hertz, MacLennan, and others, or from the quantum relation

$$V=\frac{h\nu}{e},\ \nu=(1\cdot5, s).$$

Using the value of U determined in this way for calcium, barium, strontium, hydrogen, and helium, the following remarkable results appear:

(1) About 30–40 per cent. of the Ca atoms are ionised just over the photosphere; in the chromosphere, when the pressure falls to 10^{-4} atms., almost all the Ca atoms are ionised. The same conclusion holds to a varying degree for Ba and Sr.

(2) Hydrogen and helium are not ionised anywhere in the solar atmosphere. (This is due to their high ionisation potential. V is 13·6 for H and 20·5 for He, while for Ca, Sr, and Ba the figures are 6·12, 5·7, and 5·12.) Helium can become ionised only in stars of which the temperature exceeds 16,000 K.

(3) Pressure has a great influence on ionisation, a reduction in pressure causing great enhancement of ionisation.

It therefore appears that the ionisation in the upper layers of the solar atmosphere, as revealed by the enhanced lines of Ca, Sr, and Ba, and probably also of Fe, Ti, and Sc, is due to reduced pressure and the low ionisation potentials of these elements, and not to an increased temperature.

The full theory has been worked out in a paper communicated to the *Phil. Mag.* M. N. SAHA.

Gravitational Deflection of High-speed Particles.

IN a letter published in NATURE of March 11 Prof. Eddington has shown that the statement made by me in an earlier letter to the effect that Einstein's law of gravitation seems to lead to a zero deflection for a material particle moving with the velocity of light is not in accord with the exact equation of the orbit contained in his report to the Physical Society, and suggests that my approximations were not sufficiently close to warrant my conclusion. The line element from which Prof. Eddington derives the equation of the orbit is expressed in co-ordinates which make the velocity of light different in different directions at any one point, whereas the one used by me requires that the velocity of light should be a function of position only, and not of direction. In terms of my co-ordinates the equation of the orbit of a particle moving with the velocity of light is

$$u=2\frac{m}{R^2}+\frac{1}{R}\left(1-2\frac{m}{R}\right)\cos\theta,$$

which leads to the same deflection $4\frac{m}{R}$ for a material particle moving with the velocity of light as for a light-ray. Hence it is clear that my previous conclusion was based on an insufficiently close approximation, and therefore erroneous.

I am glad to see that Prof. Eddington has verified the other principal conclusion of my letter.

Science and the New Army.

IT requires some courage to offer any opposition to the chorus of approval which has greeted the suggestion that a proportion of officers endowed with the scientific spirit should be included in the General Staff, but I venture to think that it is by no means so easy to give effect to this proposal as some correspondents in NATURE seem to suppose. No doubt it would be delightful if we could have Staff officers who knew all about everything, but in actual practice the man who does useful work in the world is a specialist in one particular subject or in one particular branch of work.

A good regimental officer requires a particular kind of training and possesses a certain set of qualifications. Similarly, a good Staff officer requires a different training and possesses a different set of qualifications. A man of science, again, is different from either of the other two.

The proportion of officers in the Army as a whole who possess any scientific training is comparatively small. There are a certain number of specialists whose ordinary duties are of a technical nature, and there are a few officers who take up some branch of science as a hobby, but the work of the average officer is not such as to bring him into touch with scientific thought and scientific methods. Men are to be found who are good Staff or regimental officers and also scientific workers, but they are exceptions, and it seems to me that a system which demands a regular supply of exceptional men is not one which is likely to work in practice.

There is also a further difficulty. Granting, for the sake of argument, that there are sufficient officers in the Army who possess both the scientific spirit and the qualities necessary for potential Staff officers, it is still necessary to devise a method of selecting them from their more ordinary fellows. Two methods are in common use, namely, examination and nomination.

An examination is a good method of testing that form of knowledge which is acquired by study, but it will be generally agreed that it is not a good method for detecting the scientific spirit. The difficulty in the case of nomination is that the candidates must be selected by ordinary regimental officers who can alone be acquainted with the qualifications of the individual candidates. The average regimental officer, however, is not himself a man of science, and I cannot see that he can ever become a judge of another officer's scientific attainments.

Without arguing, therefore, against the desirability of a General Staff containing an appreciable proportion of scientific officers, I suggest that the ideal is unattainable except in so far as specialists are attached to the Staff for their own particular work, and I think the object in view must be attained by some other means. It might be done by raising the general standard of education in scientific matters throughout the country, but this is a very large question, and not a very easy one.

Probably the best hope of an immediate improvement in the relations between science and the Army lies in the direction suggested by Prof. Filon in his letter in NATURE of April 1, in which he says:—"I would suggest . . . that what is most urgently needed for General Staff officers is a course of scientific classification and organisation, where they would be taught the real meaning of scientific qualifications and the names of living authorities in various subjects.

The position of the Signal Service is a case in point. I think I am correct in saying that a few years before the war there was scarcely an officer outside the Signal Service itself who knew what that Service was. It was generally recognised among the officers of the Signal Service that one of their chief duties would be to advise and instruct the staff in the possibilities and limitations of the Service, and that this duty would not be less important than the supervision of the technical duties of the Service itself. This principle was applied both in manœuvres and during the war, and I think that the correctness of the views held was fully borne out by experience. The ordinary Staff officer eventually learnt that battles could not be fought without signals, and that it was necessary to take the senior signal officer into his confidence if the best results were to be obtained.

I suggest that men of science in general might well follow this example. They should realise that the Staff officer is a specialist in his own particular business and that he cannot know everything, and they should themselves advise him how science can be used and what are its limitations.

Technical and scientific societies might themselves select small committees which would be prepared to advise the War Office or other Government Departments on technical matters. The committees might also be prepared to nominate gentlemen who could visit the Staff College and other military centres and give lectures on their own special subjects. The lectures would not deal with technical matters to any great extent, but their purpose would be to show what had been done by the particular science or industry during the war, and to indicate in what directions assistance might be expected in future.

One further suggestion I should like to make. Certain sums are allotted from time to time in connection with experiments on the design of military equipment, and these funds are devoted to work which is carried out almost entirely by military officers acting under the instructions of War Office Committees. The funds now allotted are small, but I suggest that additional sums might be given for research work on military subjects which might be allotted by the War Office Committees to technical or scientific institutions outside the Army. Periodical discussions between the War Office Committees and the technical institutions with regard to these researches would tend to keep the War Office Staff in touch with leading scientific and technical workers outside, and it would permit of those personal exchanges of opinion which are worth all the official letters which were ever written.

K. E. EDGEWORTH.

Crowborough, April 11.

The Universities and the Army.

THE proposals contained in the leading article in NATURE of April 8, that the raw material for the commissioned ranks should be university graduates rather than public-school boys, may be ideal, but it would have been more practicable in 1914 than it is at the present day. Under the existing pressure on the universities there is rather a risk of the Army candidate being squeezed out; there is not accommodation for all candidates for commissions to enter freely. For the moment we shall have to be content with a measure by which selected officers can be accepted at universities for specialised training not readily available elsewhere. Thus the Services can obtain that contact with living science which is so essential for them, and has been so often lacking in the past. This will require supplementing by courses within the fighting Services if proper preparation is to be made for the scientific aspects of the next war. At least at the various Staff colleges trained scientific workers must lecture, while selected officers should be sent to work in university laboratories. The present state of friendly co-operation must not be allowed to disappear.

The practice of farming out research problems to scientific institutions may have favourable results if pursued in a long-sighted manner and supported by adequate grants (and, where necessary, by field or marine trials). Given close co-operation, it should lead to many problems of defence and offence being foreseen and solved in advance. The man of science should have his chance of pointing out to those who must listen (and who have the power of decisive action) what key industries are vital to the country's safety, and cannot be allowed to pass entirely to other lands. The necessary mobilisation of science at the next emergency should be quicker and more practical, and the man of science should have a better sense of the nature of the problems that are likely to be sprung upon him to solve.

One word by way of conclusion. The fighting Services are not the only national Services that would gain by a wide infusion of scientific knowledge and method.

F. J. M. STRATTON.

Gonville and Caius College, Cambridge.

Early Hawthorn Blossom.

THE first sound of the cuckoo and the first flowers of the hawthorn have come this year about the same time, which is surely a remarkable occurrence.

It is not unusual for hawthorn blossom to appear well after the beginning of May, and it has been suggested that the discontinuance of May Day festivities was due in part to the change in the calendar introduced into this country in 1752. The change made May Day eleven days earlier by the sun, and so reduced the chance of obtaining whitethorn blossom, which was the proper ornament for the top of the maypole and for the crown of the May Queen.

Gilbert White's "Naturalist's Calendar" gives April 20 as the earliest date for the unfolding of the hawthorn blossom, but the Rev. C. A. Johns in his book, "The Forest Trees of Britain," states that hawthorn blossom was gathered in Cornwall on April 18, 1846. This year it was seen on April 16 at Northwood, Middlesex.

JENNY ROSE.

The Doctor of Philosophy in England.

REFERRING to the article in NATURE of April 15 on this subject, I may perhaps recall to the recollection of the writer that in the University of Aberdeen the degree which is primarily that of Master of Arts fers specifically *Magister Artium et Doctor Philosophiae*.

HENRY O. FORBES.

5 Ilchester Gardens, Bayswater.

Progress in Naval Engineering.

THE association between the Royal Navy and the Institute of Metals has always been close. The first president was the late Sir William White, for many years the chief naval constructor, while the fourth to hold office was Vice-Admiral Sir Henry Oram, late Engineer-in-Chief of the Navy. The institute has now elected Vice-Admiral Sir George Goodwin as its new president, and thus for the second time chosen the Engineer-in-Chief of the Fleet as its chief executive officer.

The valuable address delivered by Sir George Goodwin on assuming office dealt very appropriately with progress in naval engineering, and the way in which this has been, and may be, still further aided by metallurgical research. As he pointed out, the British Navy is the largest individual user in the world of the principal non-ferrous metals, such as copper, zinc, lead, aluminium, nickel, tin, and their numerous alloys. The standards set by the Admiralty for most of the metals required by it have always been high, and to be on the Admiralty list in the supply of such materials has always been regarded by manufacturers as a valuable asset.

Sir George Goodwin remarked that the standing problem for naval designing engineers for the last thirty years or more has been the reduction of machinery weight and fuel consumption with increased durability and trustworthiness. There were days, however, when speed was not considered in the Navy to be of great importance, and when steam power was used chiefly for auxiliary purposes in getting in or out of harbour and in calms. In those days the machinery of warships was of very much the same type as that fitted in contemporary merchant ships. Pressure for advancement began when speed was recognised as an essential condition of naval warfare, and the never-ceasing demand since then for higher speeds has resulted not only in the enormously increased power of machinery for the swift war vessels of to-day, but also in a greatly reduced weight of machinery and an increased degree of trustworthiness.

The present-day problem, as outlined by Sir George Goodwin, deserves to be stated in his own language, and is as follows :—

> In warship design offensive and defensive powers, speed, and radius of action are all tactical factors which must be taken into account. Their relative importance varies accordingly with the type of vessel and her intended service, but in all designs, once the separate values are allocated to these features, it is essential that the weight and space required for the propelling machinery should be as small as possible consistent with maintaining the desired power and degree of reliability and durability. Anything that can be saved in this direction will react on the design of the vessel as a whole, and lead to a smaller displacement and a higher speed, or, alternatively, to reduced engine power and lower fuel consumption for the same speed; or, again, on the same displacement greater offensive or defensive powers or a larger radius of action will be rendered possible. The machinery weight is, moreover, closely allied with the steam consumption of the engines at full power, and any reduction in this respect is reflected in the weight of the boiler and condenser installation with their auxiliaries.

The position reached as a result of cumulative endeavour along these lines is that in the latest British battle-cruiser it is hoped to obtain 144,000 shaft-horse-power on a total machinery weight (including water) of 4750 tons—*i.e.* at the rate of 74 lb. per shaft-horse-power; while our most recent destroyers have frequently developed more than 28,000 shaft-horse-power on a weight of 32 lb. per shaft-horse-power.

The new president then briefly reviewed the successive steps which have led to this position. He first directed attention to the application of forced draft to naval boilers, which led by successive stages to the water-tube boiler, and pointed out that this was a time of trial with worries and troubles which have rarely had an equal. Eventually, however, the difficulties were overcome. Simultaneously with this development in boilers, we passed through a stage of intense reduction in engine weight by increasing the speed of revolution of the reciprocating engine. Following upon this came the splendid realisation of Sir Charles Parsons's endeavours for many years in the production of the steam turbine, which marked an epoch in naval engineering. It was quickly turned to account, and gave us a lead which has ever since been maintained. Another direction of progress was in respect of the fuel used for power development. For many years naval engineers had directed their attention to the utilisation of oil, but only as an auxiliary to coal. The experience obtained, however, and particularly the progress made in burning appliances, were such that it was demonstrated that oil could be used as the sole fuel when security of supply could be ensured. This done, the combination of oil fuel, water-tube boiler, and turbine became the definite policy for the Navy, and finally determined the superiority which we obtained. The British Navy was the first in the field, and its designs have been adopted in principle by other navies. The most conspicuous instance of the successful performance of the above combination was afforded by the expedition of the *Invincible* and the *Inflexible* to the Falklands in the late war and its satisfactory result.

In the second half of his address Sir George Goodwin dealt with the ways in which the work of the institute could be made to serve the advance of naval engineering, and considered briefly the problems and difficulties which centre round the use of condenser tubes, turbine blading, propeller-blade materials, bearing metals, and fast-running heavy oil engines.

Condenser tubes constitute the most important instance of the use of non-ferrous materials in the Navy. Anyone who desires to become acquainted with the perplexities of Lord Jellicoe during the late war caused by the corrosion of condenser

tubes has only to study his book entitled "The Grand Fleet." The alloy used is a tin-brass containing 1 per cent. of tin, 70 per cent. of copper, and 29 per cent. of zinc. Nearly ten years ago the institute took up this very problem with the view of solving it, and has been assisted since its inception by Sir Henry Oram and Sir George Goodwin at the Admiralty. As a result, tests are now being carried out, in one of his Majesty's vessels, of a process devised by the committee's investigators, which, it is hoped, will go a long way towards solving this particular difficulty. In its work the committee has had no better friend than Sir George Goodwin, and there is a singular appropriateness about his choice as president of the Institute of Metals.

H. C. H. C.

The Investigation of Grain Pests.

By DR. A. D. IMMS.

FEW lines of biological research at the present time are of greater moment than those which are likely to contribute towards the maintenance of our food supply. Information comes from trustworthy sources that there is a considerable reduction in the available wheat of the world, and it is therefore more than ever incumbent upon us to reduce any preventable losses to a minimum. The damage sustained by stored grain through the inroads of insect pests is heavy, and we welcome a further series of the Royal Society reports [1] which are directly concerned with problems connected therewith. Prof. Dendy and his colleague, Mr. Elkington, have carried out much-needed observations of a more exact nature than has hitherto been attempted. Embodied in their reports is a good deal of both biologically and economically valuable information relating to some of our most destructive grain pests. In dealing with the phenomenon known to the trade as "webbing," they point out that it is due to the wandering of great numbers of larvæ of the moth *Ephestia elutella* over the surface of heaped grain in warehouses. Each larva trails behind itself a silken thread and, when very abundant, the whole surface of the grain may become infested with a reticulum of these threads. The superficial 12 in. of the grain are affected, and become fouled by fæcal and other larval débris. Actual injury to the grain itself does not appear to be serious, and it is probable that much of the contamination would be effectually removed during the cleaning processes to which the grain is subjected. It is, however, scarcely likely that any advantage can be derived from allowing these webs to remain, on the strength of a suggestion that weevils are destroyed through getting entangled therein. The safest and surest method is to eliminate the pest as the authors advocate, and it is noteworthy that a wide range of other food products is susceptible to the attacks of this species.

In the same report (No. 4) Prof. Dendy also deals with the occurrence of live insects in presumably sealed tins. His observations show that it is an evident fallacy to conclude that they can survive indefinitely when once the original oxygen is completely used up. The main point is to ensure that the sealing of the tins has been really efficiently carried out before the latter are relegated to the store. Directly connected with airtight storage is the question of "heating." Two experiments conducted by Prof. Dendy indicate that this process, which is due to fermentation, is prevented when the grain is stored in hermetically sealed vessels. Whether anaerobic fermentation is a factor likely to occur does not appear to have been studied. In connection with the investigations, it was noted that when a vessel is only half filled with grain attacked by *Calandra oryzae*, all the insects may become perfectly motionless in twenty-four hours. When 273·5 c.c. of air are present to 100 grains of wheat, only three insects remained alive out of thirty-nine (including all stages) at the end of fourteen days at 30°–31° C. At room temperature nineteen insects out of forty-three remained alive after thirty-two days. In both experiments the percentage of carbon dioxide had gone up to between 18 and 19, and the oxygen diminished to less than 2; and the authors express themselves as being quite certain that the insects would have succumbed soon afterwards.

It is evident from these experiments that further research under varied conditions and degrees of infestation is still desirable. If airtight storage provides ready sterilisation, without previous application of heat, we have a fact of first-rate economic significance. An important factor is the moisture content of the wheat. Above a certain point the production of carbon dioxide by wheat increases very greatly. This critical point varies with the temperature, and in the cases investigated it lies between 13·25 and 16·95 per cent. Above this critical point of moisture content wheat in airtight storage speedily renders itself immune to insect attack; below it a longer time elapses. It is noteworthy that pure (moist) carbon dioxide acts almost instantaneously as a narcotic to Calandra, but is less fatal in its effects than when mixed with a small quantity of oxygen.

The seventh report deals with points in the bionomics of *Calandra oryzae* and *granaria*, and also of *Rhizopertha dominica*, which are three of the most serious grain pests. It was found that the

[1] Royal Society. Reports of the Grain Pests (War) Committee. No. 4: "On the Phenomenon known as 'Webbing' in Stored Grain." By Arthur Dendy and H. D. Elkington. "Note on the Occurrence of Live Insects in Tins supposed to be Hermetically Sealed." By Arthur Dendy. No. 5, 1919: "On the Prevention of Heating in Wheat by means of Air-tight Storage." By Arthur Dendy and H. D. Elkington. No. 6, 1920: "Report on the Effect of Air-tight Storage upon Grain Insects," Part iii. By Arthur Dendy and H. D. Elkington. No. 7, 1920: "Report on the Vitality and Rate of Multiplication of certain Grain Pests under Various Conditions of Temperature and Moisture." By Arthur Dendy and H. D. Elkington.

optimum temperature for the breeding of Calandra is about 82° F., but somewhat higher for Rhizopertha. *C. oryzae* may increase 700-fold in sixteen weeks, which makes it a more dangerous pest than *granaria*, which has a slower rate of multiplication. On the other hand, adults of the latter species were found to survive the winter in this country at ordinary room temperature, whereas nearly all those of *oryzae* were killed off. Rhizopertha succumbs after three minutes' exposure at about 146° F., while 120°–130° F. is the lethal temperature for both species of Calandra.

As the consequence of information accumulated in the laboratory, tests along commercial lines need to be carried out in order to ascertain the practicability or otherwise of the knowledge thus obtained. We strongly urge that large-scale tests should be inaugurated with as little delay as possible. If such tests confirm the conclusion that the most satisfactory method for the storage of grain in bulk, over lengthy periods, is in airtight silos or granaries, the Grain Pests Committee is to be congratulated upon a notable achievement. The construction of such receptacles would involve a high initial cost, but probably not excessive when the annual loss from weeviling is recounted. As the authors point out, by such a method of storage we should be provided with a means of maintaining a reserve of cereals in the event of war or crop failure, and, we may add, of economic or financial difficulties.

Some Applications of Physics to War Problems.

IN an address to the Physics Section of the American Association for the Advancement of Science, delivered at the St. Louis meeting in December last and published in *Science* for March 5, Prof. Gordon F. Hull describes the work done by a number of American mathematicians and physicists in elucidating the various problems that arose during the war in connection with long-range and anti-aircraft gunnery. It may be of interest, therefore, to record the efforts of a number of British men of science, made at a much earlier date during the war, on which (and on the work of the French) the developments of American scientific gunnery as described by Prof. Hull were largely based.

Up to the spring of 1916 the developments of British ballistic science had come largely through the Ordnance Committee at Woolwich, which during the war was fortunate in having an officer of considerable mathematical attainments as head of the ballistic office. The mass of work, however, and the extraordinary variety and difficulty of the problems that arose, especially in connection with the new science of anti-aircraft gunnery, made it necessary for the Ordnance Committee to seek help from outside; and from 1916 onwards the investigation of problems in "external ballistics" devolved largely on the Anti-aircraft Experimental Section of the Munitions Inventions Department. The A.A.E.S., as it was called, consisted of a number of mathematicians and other men of science, mainly fellows and scholars of Cambridge colleges, some from the Patent Office, one from Oxford, and three fellows of the Royal Society—some in military, some in naval, and some in civilian clothes.

The work of this group was undertaken at H.M.S. *Excellent*, Portsmouth, at Rochford Aerodrome, at the National Physical Laboratory, at University College, London, and at a variety of other places. It consisted largely of trials with anti-aircraft guns, shells, and fuses, recording the positions of shell-bursts at heights up to 33,000 ft., observing and calculating the effects of winds and of pressure and temperature abnormalities, developing the mathematical theory of ballistic calculations, and investigating the behaviour or the causes of failure and irregularity of fuses. In addition to this, work of considerable mathematical and physical interest was done, some of which will be published, on the general dynamics of shell flight (such problems as the stability of shells, the effects of rotation of the earth, "drift," the "twisted trajectory of the shot," etc.), and on the pressure distribution on the head of a shell in flight. The solution of some of these problems, undertaken originally in connection with anti-aircraft gunnery, had, in the end, a considerable bearing upon the theory of gunnery in general.

The A.A.E.S., in addition to its main work in investigating the problems of gunnery, did a large amount of routine computing of range tables in conjunction with the staff of the Galton Laboratory, and performed a number of interesting and important trials on time-fuses in co-operation with the Engineering Department of University College, London. It carried out far-reaching experiments on the use of sound-locators for the detection of aircraft, and in conjunction with the R.E. and the Air Force on the co-operation between such sound-locators and searchlights; the military equipment and methods finally adopted were based directly on these experiments. It tested both the theory and the use of a number of instruments required for anti-aircraft work, such, for example, as range-finders, height-finders, and "predictors" (instruments for predicting the "future position" of the target at the moment the shell bursts); and finally it had what was known familiarly as a "travelling circus," which moved about in Great Britain and France recording the results of practice anti-aircraft shoots, and investigating the performance of guns and instruments.

The work terminated in April, 1919, and an interesting body of scientific workers was disembodied, disbanded, or demobilised. The more important practical results of their work are being recorded for the use of the military authorities: the methods adopted, however, and many of the observations, calculations, and speculations, the personalities of the men themselves, their various homes and adventures, the help (and the hindrance) they received from various people and officials, would provide material for a fascinating history of some "applications of physics to war problems" —a history, however, which will probably never be written.

Obituary.

Prof. J. A. McClelland, F.R.S.

John Alexander McClelland was born at Coleraine in 1870. Leaving the High School, he studied in University (then Queen's) College, Galway, and after a distinguished course he obtained a junior fellowship of the Royal University. Proceeding to Trinity College, Cambridge, he worked under Sir J. J. Thomson, and was one of the brilliant band of investigators who made history in those days in the Cavendish Laboratory, being contemporary with Sir Ernest Rutherford, Prof. Townsend, and others. In succession to the late Prof. Preston he became professor of experimental physics in University College, Dublin, and quickly began his famous researches on secondary radio-activity.

Shortly after becoming a fellow of the Royal Society, the National University was founded, and McClelland was appointed a member of the senate and of the governing body of University College, Dublin, positions which he held until his death. He at once devoted himself to the planning of the physical laboratory of the college. His efforts were highly successful, and a very efficient research department quickly sprang up, which accomplished wonders, considering the resources at its disposal. The number of students in the college in the beginning was 550, and at the present moment it is 1350, and the task of keeping pace with such rapid growth might easily have absorbed all the time of a lesser man; but McClelland had many other spheres of activity—secretary to the Royal Irish Academy, member of the Board of National Education, member of the council of the Royal Dublin Society, and governor of St. Andrew's College—yet he undertook a still more onerous task. He became a member of the Privy Council Committee on Scientific and Industrial Research, which necessitated frequent journeys from Dublin to London, and this during the war, when, apart from the great discomforts of travelling in those times, every crossing of the Irish Sea was a gamble with death. The constant strain was too much for him, and oftentimes his friends urged him to take a long rest. His sense of duty, however, prevented him from paying attention to his bodily weakness, and when at last the college authorities persuaded him to take a six months' rest, it was too late.

As a man of science the outlook of McClelland and his method of exposition had all the clarity of Faraday. Although, unlike Faraday, he had a sound mathematical training, his mind worked in the direction of a "common-sense" explanation of the most complicated phenomena. This made him especially valuable as a teacher, whether for advanced or elementary work. It has been the privilege of the writer to sit with him on many boards, and this same faculty of cutting away the unessentials of a question, and presenting it in its reality, rendered him a valued colleague in many matters far removed from the world of science. A Presbyterian in religion, he was followed to his grave by men of every shade of thought. It is a commonplace almost devoid of meaning to speak of a loss as irreparable, but in his college and in the wider public life of Ireland everyone who knew him feels that a man has gone from amongst us whose place it will be impossible to fill.

A. W. C.

Dr. J. G. Bartholomew.

Geographers throughout the world will recognise that scientific geography has sustained a grave loss through the death suddenly at Cintra about midnight on April 13 of Dr. Bartholomew, the head of the cartographical firm which has been known since 1889 as the Edinburgh Geographical Institute.

Dr. Bartholomew was a native of Edinburgh, where he was born on March 22, 1860, and where he was educated at the High School and the University. As a young man he entered the business founded by his grandfather. From the age of twenty-two he took an active part in its management, and at twenty-nine he succeeded his father in the supreme control. By this time he had devised the method of representing topographical features by the system known as layering, which has made the Edinburgh Geographical Institute celebrated throughout the world, and is now copied in all other cartographical establishments. Like many other novel ideas, it may seem very obvious once it has been introduced. It merely consists in the spreading of distinctive colours, tints, or shades between successive contours on a contoured map. It accordingly gives no information as to the physical features additional to that furnished by the contours; but it

makes that information available at a glance, and hence, simple as the device is, its introduction had a revolutionary effect in cartography, all the more so because it is found capable, like contouring generally, of being combined with other methods of representing physical features.

The first important work issued by the institute illustrating this new system was "The Survey Atlas of Scotland," first published in 1895, which was followed in 1903 by a similar atlas of England and Wales. Previously to that Dr. Bartholomew had published (1899) "The Atlas of Meteorology," a work of immense labour with several original features, which shows even more strikingly his zeal for scientific geography, and amply justifies the motto he had adopted, "Amore et labore." It came out as vol. iii. of a great atlas of physical geography which he had designed, but of which only one other volume appeared during his life, "The Atlas of Zoogeography," published in 1911. Much of the most devoted work of his latter years was given to the preparation of the atlas (reviewed in these columns a few weeks ago) now being published under the title of "The *Times* Survey Atlas of the World," by which he hoped to outrival the best works of the kind published in other countries.

But the Geographical Institute was far from engrossing all Dr. Bartholomew's interests. He was a member of council of the Royal Society of Edinburgh from 1909 to 1912, but in Edinburgh he was, above all, known through his intimate association with the Royal Scottish Geographical Society, of which he might with little exaggeration be called the founder. From him, at any rate, came the first suggestion of such a society, and he was among the most eager of that small body of men who in 1884 spent without stint time, energy, and enthusiasm in getting it established. He was an honorary secretary of the society from the first, and remained so until his death. By the council of that society he was generally regarded as its mainstay and chief directing spirit, and nowhere outside his family will his loss be more keenly felt than on that board.

Dr. Bartholomew was an honorary member of many foreign geographical societies. The Victoria Research Medal, a medal not awarded regularly every year, but only when there is a fit recipient, was conferred upon him by the Royal Geographical Society in 1905 "for his successful efforts to raise the standard of cartography"; and in 1918 the Helen Culver gold medal was awarded to him on like grounds by the Geographic Society of Chicago. In 1909 he received from his own university the honorary degree of LL.D. In private life he was held by all who knew him in the highest esteem, and as revealing his nature nothing, perhaps, could be mentioned more characteristic than that, in spite of the fact that he lost a son in the war, he was able to speak even of enemy countries with rare magnanimity.

GEO. G. CHISHOLM.

WE much regret to announce the death on April 18, in his seventy-third year, of DR. RUDOLPH MESSEL, F.R.S., president of the Society of Chemical Industry and past vice-president of the Chemical Society.

WE notice with regret the announcement of the death, very suddenly, on April 17, of PROF. A. K. HUNTINGTON, emeritus professor of metallurgy at King's College, London.

WE regret to record the death on April 18 of PROF. L. T. O'SHEA, professor of applied chemistry in the University of Sheffield and honorary secretary of the Institution of Mining Engineers.

MR. JAMES GAYLEY, whose death was recently announced, was the first vice-president of the United States Steel Corporation and made many important contributions to the progress of metallurgical industry. He was president in 1904–6 of the American Institute of Mining and Metallurgy and had been a member of the Iron and Steel Institute since 1888. The honorary degree of B.Sc. was conferred on him in 1912 by the University of Pennsylvania and Lehigh University; in 1906 he was awarded the Elliott Cresson medal, and in 1913 the Perkin medal, by the Franklin Institute.

MR. WILSON WORSDELL, whose death on April 14 is recorded in the *Engineer*, was born at Crewe in 1850, was educated at Ackworth, and served a pupilage in the Altoona Locomotive Works of the Pennsylvania Railroad. On returning to this country Mr. Worsdell took up an appointment with the London and North-Western Railway, and in 1883 became assistant locomotive superintendent to the North-Eastern Railway; in 1890 he was appointed chief mechanical engineer of the same railway. Up to the time of his retirement in 1910 he supervised the construction of more than 1000 engines for the North-Eastern Railway.

THE death of SIR CHARLES ALLEN on April 13 is recorded in *Engineering*. Sir Charles was born in 1851 and educated at Halifax and at a technical college in Germany. In 1872 he entered the Bessemer works at Sheffield, of which his father, who was a brother-in-law of Sir Henry Bessemer, became chairman in 1889. He succeeded to the chairmanship on the death of his father in 1899, and the remarkable success of the company, especially in later years, is due largely to his ability. Sir Charles recognised fully the value of metallurgical research, and gave every encouragement in the developments of this branch; he was closely identified with the foundation of the Bessemer laboratory at the Imperial College of Science and Technology.

Notes.

NEWS of Capt. Roald Amundsen's Arctic Expedition has unexpectedly been received from Siberia *via* Alaska. The *Maud* left Norway in June, 1918, and was last heard of some months later from Dickson Island, at the mouth of the Yenisei. According to the telegram published in the *Times*, two men left the ship in October, 1918, in the vicinity of Cape Chelyuskin. Nothing has been heard of these men, although they presumably made for the fishing settlements of the Lower Yenisei, a distance of some six or seven hundred miles across the barren tundra. There seems to be little hope that the two men are alive. The *Maud* appears to have spent last winter in the neighbourhood of Aion Island, at the mouth of Chaun Bay, in north-eastern Siberia, within six hundred miles of Bering Strait. Aion Island is noted for its reindeer pasture. The coast in the vicinity is visited by native and occasional American traders in summer. The distance to the nearest wireless station at the mouth of the Anadir is about 450 miles across rough country. Until further news arrives it would be rash to suppose that Amundsen has abandoned his trans-polar drift. It is quite possible that he intends to push into the Arctic basin north of Bering Strait in order to ensure the drift taking him to a high latitude. On the other hand, the loss of two men, even supposing his messengers to the Anadir return, will seriously weaken his expedition. Capt. Amundsen always maintained that his aims were scientific, and that he had no desire merely to reach the North Pole. It is not, therefore, probable that he will return this year, since the coast of Siberia along which the *Maud* has sailed has been explored in recent years by Russian expeditions. The *Maud* is provisioned for another three years.

THE United States National Research Council has appointed a committee on eugenics, under the Division of Biology and Agriculture, consisting of the following members:—L. F. Barker, A. G. Bell, E. A. Hooton, Daniel W. LaRue, Stewart Paton, Raymond Pearl, R. M. Yerkes, H. S. Jennings, and C. B. Davenport (chairman). The committee met on Saturday, March 20, and decided to hold the second International Eugenics Congress in New York City on September 22–28, 1921, inclusive. Dr. Alexander Graham Bell was elected honorary president, Dr. Henry F. Osborn president, Mr. Madison Grant treasurer, and Mrs. Sybil Gotto, secretary of the Eugenics Education Society, in view of her activity in organising the first Eugenics Congress, was nominated honorary secretary of the second Eugenics Congress. The national consultative eugenics bodies in the various countries will be informed of the action of the eugenics committee of the National Research Council and invited to send representatives. A general invitation will be sent to universities in different American countries and in the countries of Europe.

THE president, vice-president, and council of the Royal College of Surgeons in Ireland have elected Prof. G. Elliot Smith to the Mary Louisa Prentice Montgomery lectureship in ophthalmology. The subject of Prof. Smith's first lecture will be "The Influence of Stereoscopic Vision on the Evolution of Man." The lecture will be delivered in October next.

AN extraordinary general meeting of the fellows of the Chemical Society will be held at Burlington House on Thursday, April 29, at 5 p.m., to consider the alterations in the by-laws proposed by the council.

THE reorganisation and co-operation of research departments contemplated at the Middlesex Hospital promise to be of great value. In particular the co-operation of such distinguished investigators as Profs. Swale Vincent and McIntosh with Prof. Russ and Dr. Lazarus-Barlow may be expected to direct the investigations of cancer on the broad and general lines so necessary at the present time in this subject. We wish the new arrangements every success.

THE Report of the Salisbury Public Library for 1919–20 describes the arrangements for advancing adult education by means of a series of public lectures. A course of eight lectures was delivered by Mr. F. Stevens on the history of the neighbourhood at various periods. The lectures fell into two groups of four each, prehistoric and early historic, and were illustrated from the collections in the city museum by an inspection of the actual objects and by some five hundred photographs. The course, of which a syllabus is appended, attracted good audiences, and was so financially successful that a substantial balance remains, which is being expended in strengthening the existing collection in the library of books on Wiltshire. The committee may be congratulated on this result, and other public libraries throughout the country may use the report as a suggestion for similar arrangements.

DR. FELIX OSWALD and Mr. T. D. Price announce for publication at an early date a book entitled "An Introduction to the Study of Terra Sigillata, Treated from a Chronological Standpoint." During their excavations at the Roman station of Margidunum, in Nottinghamshire, the authors were impressed by the difficulties inherent in the study of Terra Sigillata, the so-called Samian ware, and especially by the necessity for collecting the many scattered references to the subject in many languages besides English. The importance of the study lies in the historical evidence furnished by this ware, for, apart from inscriptions, no relic of the Imperial age is more important for chronological purposes. Ample materials for the investigation are provided at sites such as Haltern, Hofheim, Newstead, and Niederbieber, which can be dated by historical evidence and from the names of the potters inscribed on their work. As the Gaulish Sigillata is a development of the Italian or Arretine fabric, a short account of this is supplied. The book promises to be valuable for the study of the Roman period in Western Europe.

IN an account of the Apalaii Indians of the Amazon (*Museum Journal*, vol. x., No. 3, September, 1919) Mr. W. C. Farabee describes a remarkable form of puberty ordeal. A frame in the shape of a jaguar, possibly an indication of totemism, is made of wicker-

work, and about a hundred wasps or ants are passed through the interstices. The youths, exhausted by a dance which is kept up all day, present themselves before the medicine-man, who applies the wasp-frame to their chests, backs, arms, and legs. Those who scream or show signs of suffering when they are stun are not allowed to continue the ordeal. Those w pass the test are invested with a headdress and flute, and deemed fit for marriage. But more than this is required. The youth must give proof that he is able to support a family by passing the target test of throwing cassava pellets at a circle drawn on a piece of wood, and of shooting arrows from a rapidly moving boat. Girls undergo the ordeal of fasting in seclusion, and their bodies are scarified with the sharp teeth of an animal or fish. They are then dressed in aprons, and use charms to stimulate affection in courtship, in which they take the initiative.

Dr. A. M. Blackman discusses in the Journal of the Manchester Egyptian and Oriental Society for 1918–19, recently issued, "The House of the Morning" in Egyptian ritual. The Heliopolitan sun-god Re-Atum was represented by his priests as re-born every morning as the result of his undergoing lustration, which was supposed to be performed by the sun-god himself, assisted by other divinities. The king of Heliopolis, high priest of the sun-god, was regarded as his son and embodiment. The lustral washing of the king-priest took place before he officiated in the sun temple, and as a result of it he was thought to be re-born like his divine prototype. His purification was completed by fumigating him with incense and presenting him with balls of natron to chew. "By being washed or sprinkled with holy water and fumigated with incense, and by the chewing of natron, the king was mysteriously re-born, brought into contact with divinities, and imbued with their unearthly qualities, and his mouth made fit to chant the sun-god's praises and recite the formulæ which accompanied the enactment of the various episodes composing the daily service in the sun temple."

It is well known that in ancient India, as described in the Institutions of Manu, the law-giver, marriage was permitted between members of different castes—a system which was forbidden by later Brahmanical legislation. Mr. Patel, one of the advanced Indian members of the Viceroy's Council, recently introduced a Bill providing that marriages between Hindus of different castes shall be valid. More conservative members opposed the Bill on the grounds that it would undermine the present social system, and that it was opposed to Hindu custom, the potent force which controls Hindu society. It was also pointed out that the enactment of such a law raised the wide questions connected with succession, adoption, and legitimacy, for which no legislation was provided in the Bill. The Government representative, Sir W. Vincent, adopted a neutral attitude, admitting that the question should be decided by public opinion carefully devoted to its consideration. If the Bill is finally passed it will be a serious blow to caste, but it is significant of the general feeling that the Mohammedan members refused to sit on the Special Committee appointed to consider it on the grounds that the question was one for Hindus, and that the latter had been obstructive on the grant of communal representation for Dacca University.

The history of science is rapidly acquiring its own periodical literature. Dr. Sarton in a recent issue of *Isis* set forth a bibliography of reviews and collections on this subject, of which he recognised sixty-two. Most of these deal with special sciences, among which mathematics and medicine take first place. Several journals are, however, devoted to the history of science as a whole. The earliest was the *Archiv für Geschichte der Naturwissenschaften*, which has appeared since 1908. Next came *Isis*, the publication of which was interrupted by the war; it has now recommenced, and will in future be in English and under the joint editorship of Dr. Sarton and Dr. Singer. The Italians have now also started a quarterly, *Archivio di Storia della Scienza*. It is edited by Prof. Aldo Mieli, who has long devoted himself exclusively to the history of science, and has printed the first volume of a monumental work on the subject. It is encouraging to historians of science that his enthusiasm has overcome the economic and social difficulties that prevail in his country, and that the publication of the *Archivio*, begun in March, 1919, is now being continued. In addition to original articles on every aspect of the history of science, it will contain reviews, a bibliography of Italian works on the subject, and notices on activities in connection with it, which are very pronounced in Italian universities. The annual subscription to the *Archivio* is 35 lire, and it should be sent to Attilio Nardecchia, Via dell' Umiltà 14, Roma 19. Information concerning *Isis* can be had from Dr. George Sarton, Carnegie Institution, Washington, D.C., U.S.A., or from Dr. Charles Singer, Westbury Lodge, Norham Road, Oxford.

Misses Blacklock and Carter contribute to the *Annals of Tropical Medicine and Parasitology* (vol. xiii., No. 4, March, 1920) papers on a mosquito, *Anopheles plumbeus*. The bionomics of this species are probably less known than those of any European Anopheline mosquito. The species is widely distributed, being met with in the British Isles, in nearly all European countries, and in the Western Himalayas, and is essentially a tree-hole breeder. Experimental evidence is produced for the first time that *A. plumbeus* is capable of becoming infected with a malaria parasite, and may therefore transmit malaria.

A suggestive review of the pathology and symptomatology of beri-beri is contributed by Dr. F. M. R. Walshe to *Medical Science: Abstracts and Reviews* (vol. ii., No. 1, April, 1920). The current hypothesis of the nature of beri-beri (a disease particularly of the East characterised by the development of neuritis) is that it is a "deficiency disease," due to the lack of certain elements or "vitamines" from the food. Dr. Walshe points out that the neuritis of beri-beri is similar to that produced by certain poisons, such as

alcohol and the diphtheria poison, and that neurologically we are dealing with no negative or defect disease, but with a definite, positive reaction of the nervous system to some unknown poison. "We know nothing of what happens in the body from the eating of a vitamine-free diet to the moment when the symptoms of beri-beri appear, and we cannot exclude the possibility that such a poison has been produced in the body." Dr. Walshe seems to agree with Eijkman that the ultimate cause of beri-beri may yet prove to be a nerve poison produced by a disordered metabolism arising out of vitamine deprivation.

A "FLORA of the District of Columbia and Vicinity," by A. S. Hitchcock and P. C. Standley, with the assistance of other Washington botanists, has been issued as vol. xxi. of Contributions from the United States National Herbarium (329 pp., 42 plates). It will replace Lester Ward's "Guide to the Flora of Washington and Vicinity," published in 1881, to which there have been six supplements. The area included is approximately a circle of fifteen miles radius, with the Capitol as the centre. The list includes all indigenous plants and all introduced ones that have become established; chance introductions are mentioned in notes appended to an allied species or genus. It is interesting to note that parts of this area are still almost wholly unexplored botanically, and the publication of the flora will afford an excellent opportunity for local botanists to supply the gaps. The arrangement is in the form of keys to the families, genera, and species, which have been carefully worked out, and also tested in the field during one collecting season; and the text is clear. An effort has been made to use common words so far as possible as substitutes for technical terms, and so-called popular names are provided for most species in the manner familiar to British botanists in Bentham's "Handbook." The Old World botanist will find some familiar plants hidden under strange names, as, for instance, Dicentra and Negundo (box-elder), which appear as Bikukulla and Rulac. The plates are a series of good photographic reproductions of aspects of the vegetation and of some of the commoner species. Unfortunately, the size of the book, large octavo, militates against its use as a pocket companion for the field botanist.

MR. J. F. N. GREEN (Proc. Geol. Assoc., vol. xxx., p. 153, 1919) has treated in his presidential address to the Geologists' Association the vulcanicity of the Lake District from a natural history point of view. He illustrates the use of petrographic details as a means of realising the conditions of intrusion and eruption, as when he pictures the scoria-cones of Borrowdale age rising above the sea and contributing their materials to the sediments by ordinary processes of erosion. He urges that the chemical analysis of an igneous rock is by itself of little value, since it cannot take into account the evanescent constituents of the magma.

FORAMINIFERA as a group always have their fascination owing to their irresolvable simplicity of organic structure and their apparent powers of selection in the up-building of their coverings. Mr. J. A. Cushman (Proc. U.S. Nat. Museum, vol. lvi., p. 593, 1919) describes "Recent Foraminifera from off New Zealand," including a new species of Technitella, a genus that forms its test of neatly arranged acicular sponge-spicules. In Bulletin 676 of the U.S. Geological Survey the same author describes Pliocene and Miocene species from the coastal plain of the United States, and shows how they help to indicate former marine climatic conditions. Mr. Cushman's wide knowledge of recent Atlantic forms renders even brief notes of this kind suggestive to the geologist.

REFERENCE has been made in NATURE (vol. xcv., p. 216) to the replacement of quartz by pyrite. A very remarkable case is now put forward by W. H. Collins in the Summary Report of the Canadian Geological Survey for 1918 (part E, p. 20, 1919) from the Michipicoten district of Ontario. The basement beds of stratified sands and gravels, belonging to the Pleistocene drift, and resting on the Keewatin iron-bearing series, have apparently been replaced by "snow-white granular silica" (presumably quartz) with a deposit of loose pyrite grains below resembling ordinary sand, and sometimes 5 ft. thick. Mr. Carus-Wilson, it may be remembered, has cited a case of the replacement by pyrite of the carbonaceous cement of an Eocene sandstone (NATURE, vol. lxviii., p. 436); but in the Canadian instance the sand-grains themselves have disappeared under the influence of solutions draining along the unconformable junction from the adjacent iron range.

THE Summary Report of the Mines Branch of the Department of Mines of Canada for the year 1918 has just been issued, and contains an interesting record of the year's activities. The fuel-testing station has been engaged, in addition to its regular routine work, upon an investigation on the carbonisation and briquetting of lignite, which promises to yield important results, as also does a test of New Brunswick oil shale in a novel type of retort—the Wallace retort. The methods adopted in Canada may be studied with advantage by those engaged in the study of carbonisation problems in this country. Good work is also being done in the ore-dressing division; until the middle of the year this had been engaged on the production of molybdenite concentrates on a working scale in view of the Empire's requirements of ferro-molybdenum for war purposes; afterwards, however, the normal working of the division was resumed and a variety of ores was tested and reported upon, the methods used being not only the ordinary wet-dressing methods, but also flotation (in a Callow cell), magnetic separation, electrostatic separation, and cyanidation. The Mines Branch may fairly be congratulated upon an excellent year's work, which must form a powerful factor in the development of the mineral resources of the Dominion.

IN the March issue of the *Decimal Educator*, a quarterly publication of the Decimal Association, there is an interesting historical account of the International Bureau of Weights and Measures at Sèvres, the establishment at which the international prototypes of the metre and the kilogram are preserved.

It is pointed out that the investigations at the Bureau have led to a vast improvement in the constancy and trustworthiness of thermometers and in the measurement of atmospheric pressure, and it is proposed to describe in future issues the instrumental equipment of the Bureau and the metrological work undertaken there. A good portrait is given of Dr. Guillaume, the director of the Bureau, who is to deliver the Guthrie lecture to the Physical Society to-morrow, April 23. In an article on the metric system it is urged that, in addition to teaching the system in schools, the Government should set a lead by adopting it in Departments such as the Post Office, the Ministry of Health, and the Royal Air Force, thus familiarising the public with metric measures and preparing the way for a change which is inevitable. Another feature of the number is an explanation of the advantages of decimal coinage.

A SUMMARY of the weather for the year 1919 has recently been issued by the Meteorological Office. It deals very fully with the annual results of the several elements for numerous representative stations for the several districts of the British Isles. The year was generally dry, and was noteworthy for the heavy snowstorm on April 27–28, and for the exceptionally cold March and November. October, which is normally the wettest month of the year, was in many places the driest. The mean temperature for the year was below the normal in all districts, the deficiency ranging from 1·6° F. in East Scotland to 0·4° F. in the south of Ireland. The earth temperatures were also below the normal, both at 1 ft. and below the surface. Rainfall was in excess in the [illegible]ern districts and deficient in the western districts. Sunshine was mostly in excess of the normal except in some of the eastern districts. Data are given showing the warmest day and warmest night, also the coldest day and coldest night, for the several stations of the different districts, and there are similar details for the several months. Monthly frequencies of sunshine for selected stations are shown. Days in the year with rainfall between fixed limits are given for selected stations, and the number of days in the year with certain maximum and minimum temperatures. Many and various particulars of anemograph observations are given, with the frequency of hours with average wind speed, also with a maximum hourly speed. A table shows the frequency of winds of various strengths from different directions for several stations in different parts of the British Isles. Much of the data is in a form which will be available for aviation requirements.

THE February and March issues of the Journal of the Franklin Institute contain the report of the committee—consisting of Messrs. E. P. Hyde, P. W. Cobb, H. M. Johnson, and W. Weniger—of the Nela Research Laboratory which undertook the investigation of the relative merits of monocular and binocular field-glasses under Service conditions. The tests are not yet completed, but already afford a large amount of valuable information. The principal conclusions of the eighty pages of the report are that in the hands of not very experienced observers the monocular requires to have a magnification of 6·27 in order to give the same results as a binocular of the usual magnification of 6·0. As regards rapidity of production and adjustment, cost, weight, portability, and ease in use the monocular is far ahead of the binocular. The report deserves careful consideration by optical-instrument makers in this country.

IN an article in the April issue of *Science Progress* Major A. E. Oxley summarises his work on the magnetic properties of about forty organic compounds between −180° and 200° C., and shows that atomic theories of the Rutherford-Bohr type, which neglect magnetic forces, are incapable of accounting for many of the magnetic properties of matter. How these theories are to be modified he is not yet in a position to say, but his diagram of two atoms held together by electromagnetic forces shows these forces to be due to a pair of oppositely directed circular currents in each atom outside the positive nucleus and rotating electrons. This idea is on the same lines as those put forward recently by Parsons (1915) and Langmuir (1919). The author points out finally that an adequate theory must account for the molecular structure of crystals, and the relations between that structure and their behaviour in the magnetic field must agree with stereochemistry, give the additive property of diamagnetics, and show no dielectric hysteresis. It is to be hoped that the forthcoming discussion on the subject of atomic structure at the Royal Society will throw some light on these difficulties of present theories.

AN important paper on the magnetic characteristics of the iron core of a transformer or of an induction coil by the late Prof. B. Osgood Peirce is published in the Proceedings of the American Academy of Arts and Sciences (vol. l., No. 7, p. 149). Sixty years ago Helmholtz verified the predictions of the mathematical theory of a transformer. The verification, however, was limited to the case when the inductances of the two coils were constant. With an iron core—the case considered by the author—this assumption is not justified. He first tried the loading coils which are used in long-distance telephony. The cores of these coils are made of iron wire only one-tenth of a millimetre in diameter. The eddy currents induced in the core are therefore negligibly small. Assuming merely the connection between the ampere-turns and the magnetisation and Faraday's law for the electromotive force induced by a change in the magnetic induction, Prof. Peirce found that the experimental results agreed with those deduced from theory to within about the tenth part of 1 per cent., *i.e.* to within the limits of experimental error. Even with the ordinary closed iron circuit commercial transformer he found that the predictions of theory were verified to high accuracy when the eddy currents in the core could be neglected. It was concluded that a good approximation to the shape of the current curves, to the rate of growth of the excitation, and to the flux of the magnetic induction in the core of a transformer can be obtained when an accurate statical hysteresis diagram of the core over the given range is available.

Our Astronomical Column.

OCCULTATION OF A STAR BY SATURN.—Bad weather prevailed generally in Europe on March 14, when Saturn occulted the star Leipzig I 4091, mag. 7·6. A few observations were, however, secured, some of them being published in *Astr. Nach.*, 5042. Prof. Plassmann observed the disappearance at Münster, noting that at 7h. 3·0m. G.M.T. the star was still separated from the limb, at 7h. 5·1m. it was in contact with it, while at 7h. 5·9m. the star had disappeared.

Messrs. K. Novak and V. Rolcik, observing at Smichow, long. 0h. 57m. 38s. E. Gr., lat. 50° 4′ 42″ N., noted the reappearance at 8h. 39m. 40s. G.M.T.

Dr. Bernewitz, at Berlin-Babelsberg Observatory, first saw the star at 8h. 39m. 34s. G.M.T. He noted that at 8h. 39m. 51s. it appeared of full brightness, and at 8h. 40m. 5s. the centre of its disc was distinctly separated from the limb. He states that the marked red colour of the star made it easy to distinguish its light from that of the planet. He made the only observation so far to hand of the appulse of Titan to the star, which occurred some four hours after emersion from the planet. He states that Titan did not occult it, but passed 1″ or 2″ to the north of it.

The extreme accuracy of Mr. Burnet's prediction is noteworthy. He gave 7h. 5m. for the disappearance, and 8h. 40m. for the reappearance. Owing to the slowness of Saturn's motion, he thought it likely that these times would be in error by several minutes.

THE EINSTEIN DISPLACEMENT OF SPECTRAL LINES.—The *Observatory* for April contains communications on this subject by Messrs. J. Evershed and C. E. St. John. The former gives reasons for thinking that the pressure in the photosphere is extremely low, so that pressure may be eliminated as a disturbing factor. Using forty-two iron lines, selected as not subject to pole effect, he obtains a shift equivalent to a recession of 0·643 km./sec. at the sun's centre and 1·000 at the limb. But observations of Venus at various elongations support the idea that this is not an Einstein effect, but a shift of all regions of the sun away from the earth. It is remarked that it is difficult to accept this as a physical reality, but no other explanation has yet been found. He notes that some of the carbon lines give an effect similar to the iron ones, but somewhat smaller. The effect seems to vary for different substances, and even for different lines of the same substance, so that some modifying influence is at work.

Mr. St. John recapitulates his well-known investigation. in which he used certain lines of the cyanogen band; he then describes his recent work on magnesium and iron lines. He finds from their weighted mean a displacement of the same sign as the Einstein prediction, but of only one-third or one-fourth of its amount. Mr. St. John notes, however, that the displacement varies with the intensity of the lines, being greatest for lines either of very great or very small intensity. As the majority of the lines measured are of medium intensity, the weighted mean is reduced. He also notes that no lines have been used which seemed unsuitable for the purpose, owing either to their proximity to others or to their instability in the arc spectrum.

STELLAR SPECTROSCOPY AT THE DETROIT OBSERVATORY.—Vol. ii. of the Publications of this observatory, belonging to the University of Michigan, has lately been distributed, and contains a great number of interesting studies of stellar spectra. Two may be instanced in particular: the study of variable stars of Class Md, by Mr. Paul W. Merrill, traces the changes of spectra that accompany the change of light, and discusses various suggestions of the cause of variability. The one favoured by the author is somewhat analogous to the "geyser" theory, but, instead of imagining a solid or viscous crust imprisoning the gases within, he substitutes a smoke-veil composed of condensing gases (calcium is especially suggested) in the upper regions of the stellar atmosphere. This would act as a screen confining the heat of the photosphere, until the accumulation of heat sufficed to vaporise the screen. When the solid-crust theory was propounded these stars were thought to be near the end of their careers as suns, but from the smallness of their proper motions it now appears that they are mostly giants.

The other paper, by Mr. Laurence Hadley, deals with the elements of ζ′ Ursæ Majoris, the first spectroscopic binary discovered. The orbit is fully discussed from several series of observations. The period is 20·53644 days, the eccentricity is 0·518, and the masses of the components $\times \sin^3 i$ are respectively 1·83 and 1·79 in terms of the sun. It is noted that Prof. Joel Stebbins finds no evidence of light variation.

Meteorology at Hong-Kong.

MONTHLY Meteorological Bulletins for the Royal Observatory at Hong-Kong for a considerable period to August, 1919, have recently been received. They contain detailed results of observations made at the observatory and the daily weather reports from various stations in the Far East, prepared under the direction of Mr. T. F. Claxton. For Hong-Kong hourly values are given of barometric pressure, temperature of the air and evaporation, direction and velocity of wind, amount of rainfall, and duration of sunshine. All the hourly observations are measured from the self-registering records. Three-hourly observations are made of the character and direction of motion of the clouds. Daily values are also given of the several meteorological elements. The normals used for comparison with the means are for the years 1884 to 1918, a period of thirty-five years. From 1916 the daily and mean hourly values of the principal meteorological records have been published in both C.G.S. and British units, and with the January Bulletins tables are given for the conversion of the several elements to the respective units. Information is also supplied for the reduction and correction of the instrumental observations. The December Bulletins give tracks of typhoons and depressions in the Far East for the year, and the divergence in the several months is well shown. With the Daily Weather Reports, which contain observations from forty-five stations in the Far East, notices are given of the warning to coast ports, which commonly state the position of typhoons when such are in progress, and forecasts are given daily for the twenty-four hours ending at noon.

The annual report for 1917 contains a comparison of the Beckley anemograph with the Dines instrument, extending over eight years; the differences are remarkably consistent until the summer of 1917, when for some unexplained reason, although noticed, the differences vary. A Richard dry- and wet-bulb thermograph has been set up to replace the Kew photographic thermograph. In section ix. reference is made to sympiesometer observations, and hourly observations are said to have been made for upwards of a year to test the popular belief in the sympiesometer as a weather forecaster. The remarks scarcely seem to refer to a sympiesometer, which was essentially a sailor's barometer in the first half of the nineteenth century. It seems rather that the instrument tested

is a camphor glass or chemical weather glass, long acknowledged to be of no real scientific value. The report for 1918 deals with the corrections to be applied to the readings of an unaspirated wet-bulb thermometer in an "Indian" shelter to reduce them to those of an aspirated thermometer at definite wind velocities and for different depressions of the wet bulb. With the lighter wind velocities, of 1–5 m.p.h., and for the larger depressions of the wet bulb, say amounting to 6°–10°, the subtractive correction to the unaspirated wet bulb amounts to 1° or slightly more. Three thousand three hundred and seventy-five observations have been dealt with, but as yet no definite scheme has been decided upon. The matter has been considered in correspondence with the British Meteorological Office.

Milk Production of Ayrshire Cattle.

THE critical genetic study of a character such as that of milk production in cattle, which is highly subject to environmental influences, cannot be carried out effectively until a fairly comprehensive knowledge of the normal variation of the character has been acquired. To this end Prof. Raymond Pearl and Mr. J. R. Miner have carried out a biometrical analysis of the normal individual variation in the milk flow and the fat content of the milk of Ayrshire cattle, the results of which are summarised in a contribution to the *Journal of Agricultural Research* (vol. xvii., No. 6). Their study is based on the records of Ayrshire cattle for the years 1908 and 1909 published in the reports of the Ayrshire Cattle Milk Records Committee of Scotland, more than three thousand records in each year being used for the purpose. Amongst the many important conclusions arrived at mention may be made of the indications that about one-half of the observed variation in milk-production results from the varying genotypic individuality of the animals with respect to this character, the remainder resulting from varying environmental influences. The udder as a secreting organ is compared with the oviduct of a hen, and it is shown that the latter operates with somewhat less variability than the former, having regard to the absolute weight of the product in the two cases.

The change in mean weekly yield of milk with advancing age is found to be represented by a logarithmic curve, the absolute amount of milk produced per unit of time increasing, though at a decreasing rate, with the age of the cow to a maximum, which was found to be when the cow is ten to eleven years old. The mean fat percentage of the milk was found to decline with advancing age until the tenth year of the cow's life, after which it remains about constant.

The Ignition Points of Liquid Fuels.

IN a paper read before the Institution of Petroleum Technologists on January 20, Mr. Harold Moore described a number of determinations of the ignition point of commercial fuels which are, or might be, used in internal-combustion engines. His ignition meter, somewhat similar in principle to that designed by Holm, consists of a steel block, heated from below, in the upper surface of which a hollow is made to take a crucible of platinum, nickel, or quartz. The air or oxygen supply passes through a hole in the block before entering the crucible, so as to pre-heat it to the temperature of the crucible, which is given by a resistance thermometer placed in a hole drilled in the block near the crucible. A cover to protect the crucible from draughts is screwed on to the block, and a drop of the liquid fuel is introduced through a hole in this cover and falls on to the bottom of the crucible. After an interval, more or less prolonged, an explosion is heard and a flame seen if the temperature is above the ignition point. This interval may be as long as thirty seconds or more, and there is no doubt that quiet combustion takes place during this period, and such combustion is very marked in the case of ether. On the other hand, the evaporation of the drops of liquid must produce local cooling, and, unless the fuel is quite homogeneous, the ignition point found must in many cases be that of the last portion to evaporate.

But, in spite of certain inherent defects, the method gives a valuable comparative test of different fuels—a test which is quick and easy to apply.

Mr. Moore recommends the use of ordinary compressed oxygen instead of air as giving more concordant results and as having a concentration at atmospheric pressures more nearly like that used in motor engines. Most hydrocarbon liquids tested in air gave ignition points from 100° C. to 200° C. higher than in oxygen; but, curiously enough, Mr. Moore found that in an atmosphere containing 70 per cent. of carbon dioxide and 30 per cent. of oxygen the ignition point of kerosene was almost the same as in pure oxygen. A few ignition points from Mr. Moore's lists may be quoted:

Ignition Point.

Fuel	In oxygen °C.	In air °C.
Taxibus spirit (Anglo-American Oil Co.) ...	272	390
Anglo-Persian oil ...	254	408
Anglo-Mexican oil ...	259	417
Normal hexane ...	287	—
Benzene ...	620	—
Ethyl alcohol ...	395	518
Ether (methylated) ...	190	347
		In silica crucible
Hydrogen ...	—	678

In the case of mixtures of two liquids of very different ignition points the addition of about 20 per cent. of the more easily inflammable liquid suffices to reduce the temperature substantially to that of the lower constituent; for instance, the addition of 20 per cent. of ether (ignition point 206°) to xylol (ignition point 555°) reduced the ignition point of the mixture to 246°.

Naval Research and Experiment.

TO ensure that the full benefits of science shall be secured to the Naval Service, a Department of Scientific Research and Experiment has been set up under the Third Sea Lord and Controller. As the Scientific Adviser of the Admiralty, and in charge of this Department, Mr. F. E. Smith, F.R.S., has been appointed with the title of Director of Scientific Research. It is the duty of the Department to keep the Navy in touch with outside scientific establishments and to ensure that the work at the various naval experimental establishments proceeds with full cognisance of scientific progress and methods. The Director of Scientific Research will work in close association with the Naval Staff, thus ensuring that naval policy is framed with due consideration of the possible practical applications of scientific progress in relation to naval needs, and enabling requirements as to types and weapons to be formulated with a knowledge of the latest scientific possibilities.

Consultations with outside scientific institutions will be resorted to, both to ensure against overlapping and with the view of utilising such of their researches and experiments as appear likely to prove of value to the Naval Service.

At present there exists under the Department a naval research laboratory at Shandon. This establishment was set up during the war with the primary object of investigating methods of counteracting the enemy's submarine menace. It has performed, and is performing, good service; but Shandon is a great distance from the experimental schools, the various scientific institutions, and the Admiralty, and it has therefore been decided that, so soon as suitable accommodation can be provided elsewhere, such of the work as requires sea environment, together with the scientific *personnel* associated with it, will be removed to a suitable existing naval establishment, and the remainder, which does not in its early stages require a sea environment, will be transferred to a naval research institute. This institute, under the Director of Scientific Research, will adjoin the National Physical Laboratory at Teddington. It will be entirely controlled by the Admiralty, but its close association with the National Physical Laboratory will offer exceptional facilities for co-operation, and the staff of the research institute will have the advantage of personal acquaintance with the work being carried out at the laboratory. The Department of Scientific and Industrial Research will be consulted in all cases when the results of investigations are likely to be of use to the general community.

To ensure effective co-operation and contact with naval thought, naval officers will frequently visit the research institute, and the scientific staff will work for lengthy periods at naval establishments, and at times go to sea

Education and Science in the Civil Service Estimates for 1920–21.

THE Estimates for Civil Services for the year ending March 31, 1921 (Class IV.: Education, Science, and Art), have now been published. Among the increased grants compared with those of last year are:—Board of Education, 12,983,094*l.*; British Museum, 74,519*l.*; Scientific Investigation, etc., 81,442*l.*; Scientific and Industrial Research, 246,845*l.*; Public Education (Scotland), 2,200,000*l.*; Public Education (Ireland), 185,735*l.*; and Science and Art (Ireland), 20,917*l.* As the Geological Museum and Geological Survey are now under the Department of Scientific and Industrial Research, their grants of 7560*l.* and 30,043*l.* respectively represent part of the increase of 246,845*l.* to that Department. The grant for scholarships, exhibitions, and other allowances to students in technical schools and colleges is increased from 17,460*l.* to 34,350*l.* In addition, there are new grants of 15,000*l.* for scholarships tenable at universities, and expenses incidental to them, and 250,000*l.* to local education authorities for maintenance allowances at places of higher education. The total amount of the grants in aid of universities, colleges, medical schools, and like institutions in the United Kingdom is about 1,000,000*l.*; there is also a special grant of 196,000*l.* for extraordinary expenditure. The grant for assistance towards the higher education of ex-officers and men of like standing is 3,000,000*l.*, compared with 2,000,000*l.* for 1919–20. The grant under the Royal Society shows an increase of 9000*l.*, and includes 2000*l.* for subscriptions to international research associations. The subjoined summary and details are extracted from the Estimates:—

SYNOPSIS.

United Kingdom and England.

	£
Board of Education ...	45,755,567
British Museum ...	294,233
National Gallery ...	29,956
National Portrait Gallery ...	9,824
Wallace Collection ...	15,953
London Museum ...	5,412
Imperial War Museum ...	50,000
Scientific Investigation, etc. ...	208,416
Scientific and Industrial Research ...	518,298
Universities and Colleges, United Kingdom, and Intermediate Education, Wales ...	945,700
Universities, etc., Special Grants ...	196,000
Serbian Relief Fund (maintenance and education of young Serbians in this country) ...	25,000
Scotland.	
Public Education ...	6,877,220
National Galleries ...	11,661
Ireland.	
Public Education ...	3,358,371
Intermediate Education ...	90,000
Endowed Schools Commissioners ...	1,042
National Gallery ...	4,650
Science and Art ...	211,415
Universities and Colleges ...	86,000
	58,694,718

DETAILS.

Scientific Investigation, etc.

Royal Society:		
(i) Grant in aid of:—		
Scientific investigations undertaken with the sanction of a Committee appointed for the purpose (including non-recurrent grant of 5000*l.*) ...	11,000	
Scientific publications ...	1,000	
Subscriptions to international research associations ...	2,000	
		14,000
(ii) Grant in aid of salaries and other expenses of the Magnetic Observatory at Eskdalemuir ...		1,000
Total for Royal Society ...		15,000
Royal Geographical Society ...		1,250
Marine Biological Association of the United Kingdom ...		1,000
Royal Society of Edinburgh ...		600
Scottish Meteorological Society ...		100
Royal Irish Academy ...		1,600
Royal Irish Academy of Music ...		300
Royal Zoological Society of Ireland ...		500
Royal Hibernian Academy ...		300
British School at Athens ...		500
British School at Rome ...		500
Royal Scottish Geographical Society ...		200
National Library of Wales ...		12,000
National Museum of Wales ...		15,500
Solar Physics Observatory ...		3,000
North Sea Fisheries Investigation ...		1,250
Imperial Mineral Resources Bureau ...		10,750

	£
Royal Academy of Music	500
Royal College of Music	500
Medical Research Council	125,000
British Institute of Industrial Art ...	5,500
Edinburgh Observatory	2,566

Department of Scientific and Industrial Research.

Salaries, wages, and allowances	29,235
Travelling and incidental expenses ...	1,950
Grants for Investigation and Research:	
(1) Investigations carried out by learned and scientific societies, etc.	13,800
(2) Investigations directly controlled by the Department of Scientific and Industrial Research	40,928
(3) Students and other persons engaged in research	38,300
(4) Expenses of Research Boards for co-ordination of Government research ...	200,000
Total	293,028

Fuel Research Station	40,882
Geological Museum	7,560
Geological Survey of Great Britain ...	30,043
National Physical Laboratory[1]	203,000
Appropriations in Aid:—	
Contributions of co-operating bodies ...	1,550
Refund of unexpended balance of grants	300
Testing fees at Fuel Research Station ...	1,000
Sales of by-products at Fuel Research Station	2,500
Testing fees at the National Physical Laboratory, charges for special investigations, and repayments by the Road Board, India Office, etc., for services rendered by the National Physical Laboratory	55,000
Balance of accrued interest at March 31, 1921, on the Fund of the Imperial Trust for the encouragement of scientific and industrial research, for which 1,000,000*l.* was voted in 1917–18	27,650
Total for Appropriations in Aid	87,400

Universities and Colleges, United Kingdom.

Birmingham University	35,000
Bristol University	17,000
Bristol Merchant Venturers' Technical College	2,000

Universities and Colleges, United Kingdom, unallocated grant	210,500
Total for Universities and Colleges, United Kingdom, Grant in Aid[4]	916,000

[1] Services rendered without payment for other Government Departments are estimated as follows:—Admiralty, 7,500*l.*; Air Ministry, 40,000*l.*; Ministry of Munitions, 7,000*l.*; War Office, 2,150*l.*; H.M. Office of Works, 500*l.*; Board of Trade, 1,000*l.*; Works undertaken at the instance of the Advisory Council, 8,000*l.*

[2] This sum includes 42,000*l.* payable to Scottish Universities under Section 25 of the Universities (Scotland) Act, 1889, and is in addition to an annual sum of 30,000*l.* payable to these Universities from the Local Taxation (Scotland) Account under Section 2(2) of the Education and Local Taxation Account (Scotland) Act, 1892.

[3] In addition to 84,000*l.* provided in Class IV., 18.

[4] This sum, together with 84,000*l.* provided in Class IV., 18, is intended to raise to 1,000,000*l.* the total amount of the grants paid out of the Exchequer during the year 1920–21 for the maintenance of University Institutions in the United Kingdom.

The Native Tribes of Western Australia.

At a meeting of the Royal Anthropological Institute on April 13, Sir Everard im Thurn, president, in the chair, Mr. G. O. Neville read a paper on "The Aborigines of Western Australia: Their Treatment and Care." In introducing the speaker, the president laid stress upon the importance of papers dealing with the practical side of native questions. It was often said that the Government did not assist scientific societies enough, but he was sometimes in doubt whether scientific societies on their side gave sufficient assistance to the Government.

Mr. Neville said that the aborigines of Western Australia were most numerous in the north, diminishing as they came nearer civilisation, until almost extinct where the white man has lived since the early days of occupation. By nature a nomadic race, they live by hunting alone and cultivate nothing. They communicate with each other by means of a cipher, intelligible only to themselves, cut upon message sticks, or *Bambarro*, the bearer of which is granted a safe passage through hostile tribes. Numbers of crude figures, representations of beasts, birds, or reptiles, are to be found drawn in coloured pigments upon flat rocks or inside caves in the far north. The gradual disappearance of the natives continues unceasingly, in spite of constant effort. This is due to change of food, their hunting-grounds being occupied by the squatter, and the necessity for their having to clothe themselves and live more or less under shelter. The aborigines do not believe that any person dies a natural death, but suppose the deceased to have been *boulyaed* (bewitched) by some member of another tribe, and it becomes the duty of a near relative, generally a brother of the dead person, selected by the *Bulyas* or medicine-men, to avenge his death by killing the supposed murderer or another one of the tribe to which the murderer is supposed to belong. One of the most remarkable means of disposing of the dead, known as the stone system, occurs in the north. There the body of the dead person is elevated to a platform of sticks built in a tree, a layer of large stones being placed immediately beneath the body. The stones represent individuals who might have caused the death of the victim; and if the fat from the body, evaporating in the heat of the sun, falls upon any stone, the individual represented by that stone is the one upon whom vengeance will sooner or later fall at the hands of the near relatives of the deceased person. If no fat falls, a near relative will, after the removal of the body to an adjacent ant-heap, where only the bones are soon remaining, sleep upon the pile, and it will be revealed to him in a dream which is the selected stone.

No native can be employed except under a permit issued by a Protector. Generally speaking, the treatment of Western Australian natives at the hands of their employers leaves little to be desired. The Aborigines Act provides the necessary machinery for bringing offenders to book. The Chief Protector being constituted by law the legal guardian of every aboriginal and half-caste child until the age of sixteen, it is possible to remove any child from undesirable surroundings. Some eighty Protectors, under the Chief Protector, are resident in various parts of the State where there are natives. Seventy Government relief stations provide assistance for indigent and destitute natives. The Department owns cattle settlements in Kimberley, and two farming and industrial settlements have been established recently in the south for the reception of indigent and aged people, with special provision for the care and training of orphan children. The reserves upon which these settlements are established are for the natives only, and whites, other than the staff employed, are rigidly excluded by law. The provision of medical attendance has been the special care of the State; all natives receive free advice, medicine, and hospital treatment in case of sickness. The nine mission stations in Western Australia, nearly all subsidised by the State, have done useful work, especially in the care and rescue of children. Though the people are dwindling away, the work of the Department must go on, in the hope that the last days of a dying race can be made the easier and happier.

In declaring the subject open for discussion, the president said that the cause of the decrease in a native population when it came into contact with civilisation was its failure to adapt its psychological constitution to changed circumstances.

Dr. Corney said that as a result of his experience in dealing with immigrant labour—male only—in Fiji, he had arrived at the conclusion that the type of soil had an important effect on certain groups; for instance, an alluvial soil was fatal to Gilbert Islanders and Solomon Islanders, although the former throve on sandy soil such as that of the islands on which coconuts were grown, and the latter made excellent sailors. It was also evident that all were peculiarly susceptible to the attacks of micro-organisms from which the European population was to some extent immune, as shown by the virulence of the epidemics of measles and influenza.

Mr. N. W. Thomas pointed out that Pater Schmidt has shown that in the north mode of burial and language coincide in distribution, and asked whether the distribution of drawings also coincided with platform burial and language.

Prof. Arthur Keith said that if we were placed in the Australian desert and asked to live the life of the aborigines, he doubted whether we would survive. Would we not rather die as they die in our environment? When they were brought into contact with our civilisation we asked them to make a jump of perhaps two thousand generations within a lifetime; to change at once from the life of a prince to that of civilisation, the life of a horse in a mill. The governing factor in deciding the fate of native populations lay in the domain of psychology. Here the man of science came into touch with the practical problem, for he was trying to understand the back of the black man's mind.

Miss Freire-Marreco compared the measures adopted in Western Australia with those which had been followed in the United States of America, especially in relation to the dying out of the native races. Until about ten years ago the native races there had diminished rapidly. Since then, however, the Indian population had been on the up-grade, owing largely to the attention paid by the Central Government to the food-supply and the checking of tuberculosis and other diseases by isolation and the inculcation of sanitary and hygienic rules.

University and Educational Intelligence.

Mr. F. A. Heron has given to Queen's University, Belfast, the sum of 5000*l.* to provide the necessary equipment for teaching physical chemistry, and 1000*l.* towards the provision of accommodation for the department.

In connection with the faculty of medicine of the University of Birmingham, a course of ten weekly lectures (free to medical men) on "Principles of Psychotherapy" is to be given by Dr. W.

McDougall, F.R.S., in the medical school buildings of the University, beginning on Friday, April 30.

THE subject for the Jacksonian prize of the Royal College of Surgeons of England for 1921 is "The Pathology, Diagnosis, and Treatment of Tuberculous Disease of the Spinal Column with its Complications."

APPLICATIONS for not more than three Ramsay memorial fellowships for chemical research will be considered by the trustees at the end of June next. They must be received by, at latest, June 15 by Dr. W. W. Seton, organising secretary, Ramsay Memorial Fund, University College, Gower Street, W.C.1. The fellowships will each be of the annual value of 250*l*., with, possibly, a grant of not more than 50*l*. per annum for expenses, and tenable for two years, with the possible extension of a year.

DR. J. H. ANDREW has been appointed to the chair of metallurgy in the Royal Technical College, Glasgow, vacant by the transfer of Dr. Desch to the University of Sheffield. Dr. Andrew graduated in Manchester University with first class honours in chemistry. After research work in metallurgy, he received the M.Sc. degree in 1908, and was awarded the Dalton scholarship. He continued metallurgical investigations in the University laboratories until 1914, was appointed research fellow and demonstrator in 1910, and Carnegie scholar of the Iron and Steel Institute. He received the degree of D.Sc. in 1915. Since June, 1914, Dr. Andrew has been chief of the Metallurgical Research Department of Sir W. G. Armstrong, Whitworth, and Co., Ltd., Manchester, and has gained a wide experience in the metallurgical industry, having had unlimited scope for studying practice and for research. His publications include a number of important papers presented to the leading metallurgical societies.

Societies and Academies.

LONDON.

Royal Microscopical Society, March 17.—Prof. John Eyre, president, in the chair.—T. E. **Wallis**: The lycopodium method of quantitative microscopy. Various methods have been devised by different workers in an attempt to find a satisfactory method of making determinations of percentage composition by means of the microscope. The most trustworthy of these require specially constructed apparatus and are applicable in certain instances only. The Lycopodium method is simple in principle, and with slight modifications may be used for all kinds of problems. The only apparatus needed is such as is used in ordinary microscopical work. The results are correct to within 10 per cent. of the amount to be determined; they can therefore be utilised with the same confidence as is the case with results obtained by many well-known chemical operations having a similar range of error.—C. **Da Fano**: Method for the demonstration of the Golgi apparatus in nervous and other tissues. The author has been able to obtain a fairly constant staining of this peculiar intracellular formation by substituting cobalt for uranium nitrate in a formula originally proposed by the Spanish biologist, S. Ramon y Cajal. Da Fano's modification can be easily applied to all sorts of tissues, as proved by an interesting series of quite demonstrative microscopic preparations and lantern slides shown at the meeting. Another step has thus been taken in the study of the "internal apparatus" discovered by Golgi in 1898, the functions of which, however, still remain quite mysterious to biologists and physiologists.

Linnean Society, March 18.—Dr. A. Smith Woodward, president, in the chair.—Prof. J. **Small**: The chemical reversal of geotropic response in roots and stems. It was stated that when roots are placed horizontally in a moist atmosphere rendered very faintly alkaline by ammonia vapour they tend to grow upwards. When stems are treated in a similar way with acetic acid vapour they tend to grow downwards. These experiments form preliminary confirmation of a theory of geotropic curvature which has been elaborated as a correlation of previous work on the electrical conductivity of roots with data accumulated by other investigators.

Aristotelian Society, March 22.—Prof. Wildon Carr in the chair.—Clement C. J. **Webb**: Obligation, autonomy, and the common good. It was contended that the notion of obligation in which Kant rightly found the essential feature of our moral consciousness cannot be directly derived (as Green seems to suppose) from the notion of a "common good"; that, on the contrary, the notion of a "common good," and the closely connected notion of a "general will," derives its significance for ethics, and eventually for politics also, from its connection with the notion of obligation; and that this makes it necessary for any truly ethical conception of the State to retain the idea of "authority," as ascertained, indeed, through the general will, because only thus can it be recognised as authority—viz. the community for itself; not, however, as in itself merely the result of the general will, but as the expression of an absolute factor therein, which perhaps may be best described as the sovereignty of God. To the thought expressed in Kant's choice of the word "autonomy" to express the status of the good will may be traced along one line of descent the anti-authoritarian tendency in contemporary ethics and politics.

Geological Society, March 24.—Mr. R. D. Oldham, president, in the chair.—Mrs. Eleanor M. **Reid**: Two pre-Glacial floras from Castle Eden (County Durham). The seeds examined were obtained by Dr. C. T. Trechmann from pre-Glacial clays, found in fissures of the Magnesian Limestone at Castle Eden. The clays were carried by the Scandinavian ice from the area now covered by the North Sea. The study proved the presence of two seed-bearing clays of different ages, the earlier being undoubtedly Pliocene. The Pliocene age is confirmed by M. P. Lesne, who determined the insect remains found intermingled with the seeds. While the work was in progress material from the base of the Pliocene of Pont de Gail (Cantal) gave knowledge for the first time of a seed flora of known age, low down in the Pliocene; it showed that the rate of change in the character of the West European Pliocene flora was slower than had been suggested by Clement Reid and the author. A critical comparison was made between the Cromerian, Teglian, Castle Eden, Reuverian, and Pont de Gail floras on the bases of the percentages of all exotics, and of Chinese-North American exotics—that is, plants now inhabiting the Far East of Asia or North America, but not Western Europe—in each flora. The result proved the Reuverian to be Lower Pliocene, not top of the Middle Pliocene (as formerly suggested), and the Castle Eden flora to be Middle Pliocene. Therefore a study of fossil seeds had made it possible to discriminate between strata intimately mixed *in situ*, and to determine their geological age when unknown.—Mrs. Eleanor M. **Reid**: A comparative review of Pliocene floras, based on the study of fossil seeds. By plotting as a curve the percentages of all exotics, and of Chinese-North American exotics, from the five floras (see above paper), it was found that all lay

along a smooth curve, part of which indicated changes in the Pliocene and part in the Miocene. From this curve certain deductions are drawn, namely: (1) The study of living and fossil seeds can lead to accurate specific determinations. (2) The study of fossil seeds is as accurate a method of determining geological age as is palæontology, and the age indicated for the Reuverian and Castle Eden floras is approximately correct. (3) The destruction and supplanting of the Chinese-North American exotic flora began about the Middle Miocene, at the time when the great European and Asiatic Alpine ranges attained their maximum uplift; but it was to these trans-continental barriers that Clement Reid and the author attributed the extermination of this flora. Therefore, the curve gives strong and independent confirmation of the truth of their theory, and is in accord with the findings of stratigraphy and palæontology. (4) The curve indicates an incoming flora—the present flora of Western Europe and, in part, of Central and Southern Europe—which first appeared in the Miocene. Of this the aquatic element is now chiefly circumpolar in distribution, whereas the dry-soil element mainly centres in the Himalayas. (5) The incoming flora only in part survived in Western Europe; the destruction became greater after the Middle Pliocene; the cause of this is unknown.

Cambridge.

Philosophical Society, February 23.—Mr. C. T. R. Wilson, president, in the chair.—Prof. **Seward**: The origin of the vegetation of the land. A brief consideration of questions raised by Dr. A. H. Church in a recent memoir on "Thalassiophyta and the Subaerial Transmigration" (Oxford, 1919). "The beginnings of botany are in the sea." Life evolved from the ionised water of a continuous world-ocean two miles in depth. The plankton epoch; unicellular, free-floating plants. The Benthic epoch was initiated when portions of the earth's crust rose to within the reach of light and plants were able to establish themselves on the ocean-floor. Development during the Benthic epoch of complex anchored marine plants. The epoch of the land flora began with the emergence of areas of land and the transference of plants from the hydrosphere to the atmosphere.

Manchester.

Literary and Philosophical Society, March 2.—Sir Henry A. Miers, president, in the chair.—W. J. **Perry**: The search for gold and pearls in Neolithic times. Further research on the distributions of early sites of civilisation and of the sources of gold and pearls has produced a mass of evidence to substantiate and enlarge the thesis of an earlier paper by the author on "Megalithic Monuments and Ancient Mines." The evidence now suggests that not only megalithic monuments, but also early sites in general, marked the settlements of seekers after gold and pearls, amber and purple having also played their part in attracting strangers. These settlements are mostly localised in the basins of rivers containing gold or pearl-bearing mussels, and the distribution map shows that the early seekers for these objects did not allow much to escape them. Further inquiry will be necessary in order to determine the precise age when this search began.—C. L. **Barnes**: Einstein's theory of space and time.

Edinburgh.

Royal Society, March 1.—Prof. F. O. Bower, president, in the chair.—Prof. J. C. **Ewart**: The nestling feathers of birds. This paper embodied certain facts of observation in regard to the development of nestling feathers which did not harmonise with the view generally taken that feathers were originally developed out of scales. Three facts of fundamental importance should be borne in mind: (1) The geological record has hitherto told us nothing about the evolution of feathers; (2) the embryological record affords no evidence in support of the view that scales grew longer and lighter and, after much spreading and splitting, became feathers; and (3) the true feathers of modern birds are, as a rule, derived from small umbels consisting at the outset of barbs, which result from the splitting of the intermediate layer of cells of a simple dermic papilla similar to the papillæ of the tongue of ducks. A study of simple nestling feathers (prepennæ) leads one to believe that the plumage of primeval birds consisted of umbels (protoptiles) which differed but little from the bundles of hair found in the jerboa and certain other mammals, or of umbels consisting of barbs armed with barbules, as in the feathers forming the first nestling coat of penguins, or of feathers with practically all the structures now associated with true feathers. In course of time feathers of a different type were evolved, which, as they grew, pushed from the skin, and for a time carried on their tips the feathers of the first generation. The second kind of feathers (mesoptiles) are now well represented in penguins and in the emu, and a remnant is still found in ducks and geese; whether the body of Archæopteryx was clothed with protoptiles or with mesoptiles or with plumose feathers it is impossible to say. When all the facts recently established by a study of the development of feathers are duly considered, there is no escape from the conclusion that the wing-quills are only highly specialised nestling feathers, and that it is inconceivable that the first nestling feathers were formed out of scales.—Dr. J. M'Lean **Thompson**: New stelar facts and their bearing on stelar theories for the ferns. In order to know how the complicated vascular system of adult ferns came into existence, knowledge of individual development was necessary. This has now been traced by sections in a number of specially chosen cases, and the results reconstructed into diagrams showing the individual advance. This involves the formation of a pith, inner phloëm, inner endodermis, and frequently, in the early stages of development, pockets of outer endodermis. These tissues are new creations within the vascular system formed by a static change of quality of the elements from the growing point. The solenostele and other higher forms of the vascular system arise by further modification of the structures thus acquired. This involves the formation of gaps in the vascular system, through which the pith and cortex, originally distinct, unite to form one continuous tissue. The ferns dealt with range from the primitive Schizæaceæ to the advanced Pterideæ.—Sir Thos. **Muir**: Note on Pfaffians with polynomial elements.

Paris.

Academy of Sciences, March 22.—M. Henri Deslandres in the chair.—A. **Lacroix**: The eruptive rocks of the Pyrenees Cretaceous and the nomenclature of the modified eruptive rocks.—G. **Bigourdan**: The pupils of the Observatory of the Collège de France. The observatories of the Military School.—F. E. **Fournier**: General expressions for the resistance of water to the passage of ships floating in open air and for the wavelength of their satellite surge.—A. **Haller** and R. **Cornubert**: The constitution of the dimethyl*cyclo*hexanone obtained by methylation of the sodium derivative of α-methyl*cyclo*hexanone. From a study of the condensation products with benzaldehyde it is concluded that the dimethyl*cyclo*hexanone is unsym-

metrical.—H. **Lecomte**: The tier-like structure of certain woods.—P. A. **Dangeard**: The structure of the plant-cell and its metabolism. A critical discussion of the views of Guilliermond.—M. Maxime Laubeuf was elected a member of the division of the applications of science to industry.—N. E. **Nörlund**: A theorem of Cauchy.—Ch. **Fremont**: Work done in sawing metals by hand. A diagram and description of a pendulum support and guide for a hack-saw. There is an economy of about one-third of the labour.—J. **Vallot**: The calibration in calories of two actinometers adapted to studies in heliotherapy and agricultural climatology.—J. **Guillaume**: Observations of the sun made at the Observatory of Lyons during the fourth quarter of 1919. Observations were possible on sixty-six days during the quarter, and the results are tabulated, showing the spots, their distribution in latitude, and the distribution of the faculæ in latitude.—M. **de Broglie**: The K absorption bands of the rare earths for the X-rays.—P. **Boucherot**: Electrical resonance in a circuit the self-inductance of which contains iron.—C. **Chéneveau** and R. **Audubert**: A nephelometer.—P. **Job**: The constitution of two cobaltammines.—J. **Guyot** and L. J. **Simon**: The combustion by mixtures of sulphuric and chromic acids of organic bodies containing chlorine. Whilst the combustion of hydrocarbons by the wet method is nearly always incomplete, out of nine chlorinated hydrocarbons seven gave correct figures for carbon and only two, pentachloroethane and hexachloroethane, gave low results.—C. A. **Kténas**: The hydrocarbon zone of Western Greece. Sixteen points are marked on a map of Western Greece where indications of oil, bituminous schists, or asphalt have been found.—P. **Fallot**: Observations on drift phenomena in the centre of the Sierra of Majorca.—C. **Störmer**: The absorption of the penetrating corpuscular rays in the earth's atmosphere following non-rectilinear trajectories.—G. **Reboul** and L. **Dunoyer**: The utilisation of cirrus clouds for weather prediction. Rules are given for weather forecasts based on the appearance of cirrus clouds, their displacement and amount. Results of the application of these rules to weather predictions are compared with the observed weather.—V. **Bjerknes**: The temperature of the upper layers of the atmosphere.—G. **Nicolas**: The respiration of plants carrying parasitic fungi.—H. **Coupin**: The time taken by cholorophyll to develop its maximum intensity in the light.—P. **Portier**: Modifications of the testicle of birds under the influence of a diet free from vitamines.—J. **Athanasiu**: The supposed dynamogenic power of alcohol. There is no evidence of increase of muscular power at any period of time after ingestion of alcohol. The experiments described afford a further proof that alcohol is not a food utilisable by the organism.—J. E. **Abelous** and L. C. **Soula**: The action of secretin upon metabolism.—F. **Diénert**: The formation of activated sludge.—A. **Fernbach** and M. **Schoen**: New observations on the biochemical production of pyruvic acid. During the fermentation of sugar by yeast in a solution maintained neutral by chalk an appreciable quantity of pyruvic acid is formed.—J. **Legendre**: The *rôle* of domestic animals in the defence against malaria.

Rome.

Accademia dei Lincei, Class of Physical, Mathematical, and Natural Sciences, January 18.—Prof. A. Ròiti, vice-president, in the chair.—O. M. **Corbino**: A laboratory method for the production of continuous and constant electric currents of high tension.—G. **Ciamician** and C. **Ravenna**: Influence of some organic substances upon the development of plants (iv.).—A. **Angeli** and C. **Lutri**: Chemical researches on the melanins of pyrrole.—Q. **Majorana**: Gravit[illegible] A continuation of previous researches (1918) on a rather sensational subject, namely, the screening off of gravitation by a massive spherical sheet (in practice, about 100 kg. of mercury placed between two concentric spheres). Last May the author found, or at least believed he had found, a positive effect, *e.g.* a just discernible diminution of the weight of a sphere of lead placed within the cavity of the said sheet; but later he found a slight increase in the weight instead. In the present note the author gives some further details about the improvement of his apparatus, and discusses possible perturbations of thermal and mechanical origin. The net results of his search for a gravitational screening effect are so far inconclusive.—F. **Bottazzi**: Researches on the posterior salivary gland of Cephalopodes (iii.). This note deals with the independence of secretive activity of the presence of free oxygen.—E. **Bompiani**: Metrical invariants and covariants with respect to surface deformations of higher order (species) (iii.).—A. **Rosenblatt**: A theorem of Liapounoff (to be published in the next issue of the *Atti*).—L. **Tonelli**: Primitive functions. An old mathematical subject re-inaugurated about twenty years ago by Lebesgue and others.—E. **Zavattiero**: Relation between the resistance and stress in bismuth.—C. **Ravenna**: Preliminary note on the synthesis of a peptide from aspartic acid with vegetable enzymes.—G. **Sani**: Arbusterine and its derivatives.—L. **Bernardini**: Nicotine in tobacco. A contribution to the study of the genesis and the functions of alkaloids.—E. **Pantanelli**: Influence of nutrition and radical activity upon collapse produced by cold.—A. **Trotter**: The supposed parthenocarpy of the hazel-nut and its possible characters (ii.). Results of observation and experiments are given.

1920.

of German

IN 1916, as a result of war conditions, British chemical manufacturers formed an association with the view of strengthening and consolidating their position by mutual help and co-operation. After the declaration of the armistice the association dispatched a Mission to Germany, under the guidance of the Department of Overseas Trade, to study the present position of German chemical industry. The Mission consisted of twenty members of the association, representing various branches of chemical manufacture, and it was accompanied by a military representative and by delegates of the Department of Overseas Trade, the Board of Trade, the Local Government Board, and Canadian interests. Thirty-nine works were visited, all of them in German Rhineland and in zones occupied by the Allies from north of Cologne to Mannheim. The inquiry resolved itself into a study of the position of the following sections of chemical industry, as developed in Germany, viz. (1) Heavy chemicals; (2) coal-tar products, intermediates, and dyestuffs; (3) fine organic and pharmaceutical products; (4) general inorganic products.

The report of the Mission is of the highest public importance, and merits the attentive consideration of every chemical manufacturer in the kingdom. It is, however, too technical to be dealt with here. We are concerned rather with its general purport and with the lessons and warnings it conveys. These are given in the summary of the report which the association has caused to be printed and published.[1] We trust it will be widely circulated and read. The moral it inculcates is summed up in this one brief sentence: "*German chemical industry has been one stupendous organisation for effecting and promoting the application of science to industry*"—a statement which, we agree with the writer of the summary, "should be displayed, not only in every office, but in every educational institution in the kingdom," as well as "in all Government Departments."

At the same time, there is nothing very new in this pronouncement. It has been the burthen of innumerable articles and public addresses during the last half-century; and we see their effect in the multiplication of our provincial universities and the creation of our various technical colleges and schools. Anyone at all familiar with the history of these institutions knows that their creation has been entirely due to the action of a few public-spirited men who have laboured, in season and out of season, and often under sore discouragement, to effect their establishment. In no single instance have they been due to the spontaneous impulse of a whole community, prompt to recognise and to appreciate the value of science to industry. Even when established, there was, as a rule, no very widespread desire, at all events at the outset, to take advantage of the opportunities they afforded. In most of them their day of small things was a fairly long period.

But the coming of the war brought a great awakening. The national importance of science was recognised as never before. We then realised we were confronted with a nation that had sedulously cultivated science in its application to practically every art and every industry of peace, as well as of war, and we were amazed and disquieted at our own shortcomings and our supine neglect. The new Education Act is a measure of the degree to which the country has been roused. The ease and practical unanimity with which it was passed are the clearest proofs of the public conviction of its necessity.

The document before us, emanating from a body of experts eminently qualified to express an authoritative opinion, will serve to strengthen that conviction. It deals, of course, mainly with only one branch of applied science; but, as it happens, it has been a branch which has rendered extraordinary service to the country at one of the most critical periods of its history. It was not so much our knowledge of chemistry that helped us, or the facilities we possessed of applying it. In these respects we were lamentably behind our chief enemy, and that enemy knew it. But she reckoned without the national characteristics which ultimately saved the situation, and, luckily for us and the world, her lightning stroke missed its aim, and she was compelled by circumstances to give us time to develop and apply them. But it is safe to say that, had we been capable of taking up the position before the war that we were in at its close, its duration would have been greatly curtailed, and it is conceivable, indeed, that it would never have been begun.

The summary of the report, concise as it is, covers more ground than can be dealt with in a single article. We must therefore confine our-

[1] A Summary of the Report of the British Chemical Mission on Chemical Factories in the Occupied Area of Germany. (Association of British Chemical Manufacturers, 166 Piccadilly, W.1.)

K

selves to a brief statement of the general impressions which the members of the Mission gained concerning the present development of chemical industry in Germany, and its potential future as affected by the war.

To begin with, the Mission was strongly impressed with the evidence of scientific method which appertained to everything relating to the industry, not only to the laboratory and the factory, but also to accountancy, buying and selling, and the management of labour—in fact, to every side of business activity. This result had been achieved by an efficient combination of experts. "The Germans, in fact, have learnt how to use their leaders with utmost effect." It has been the fashion to disparage the originality of the Germans and to point to their lack of inventive power. Whatever may be their failings in these respects, there is no question that it is through their willingness to co-ordinate their efforts that much of their striking success is to be attributed. Moreover, as is pointed out, the chemical industry occupies a high position in Germany, and it can command the services of the best brains in the country. The status of the chemist is such that it is now, at least in the higher positions, one of the best paid of the professions in Germany—far more so than the Law and the Church. How this has been brought about is clearly stated:

> "During generations past, unlimited facilities have existed for providing those who wish to become chemists with an education which is nowhere excelled, so that not only is the status of the chemist high, but the man himself, in virtue of his thorough training, is fitted to maintain the high position in which he is placed. Everywhere the chemist is to the fore, and not only are chemists found in the chief administrative positions of the large chemical undertakings, but they frequently control the great organisations characteristic of German industry generally."

The author of the summary has a very definite opinion as to the influence of the German educational system in the universities and the polytechnics in reaching this result, and he contrasts it with our own system of scholarships and bursaries, which he evidently disparages:

> "As German education has been carried on without money bribes in the form of scholarships and fellowships, and without competitive examinations, the system has been one of almost complete *Lernfreiheit*. Although it has often been adversely criticised by those unacquainted with its workings, the results belie all such criticism. At least, the student has always worked with a forward outlook; his effort has been to *solve a problem*, not merely to acquire knowledge. The system has been as far removed as possible from that pursued in this country, especially at Oxford; there can be little doubt that it has been a factor of great importance in the development of industry on a scientific basis in Germany."

Now, while there is much that is unquestionably true in this statement, in his desire to decry our own educational system the writer has shown either that he himself is not wholly acquainted with the later development of the German system, so far as it is concerned with chemistry and its industrial application, or that he is guilty of a *suppressio veri*. The German leaders of chemical industry some time ago determined to attract promising chemical students by that very system of "money bribes" which he deprecates, and to endow what are practically fellowships to be held in connection with German university laboratories. In principle there was nothing in this essentially different from our own procedure—except that the aims of the German manufacturers were not quite so altruistic as those of the "pious founders" in our own universities.

The writer of the summary pays a well-deserved compliment to the enterprise, skill, and courage of the men who controlled these vast industrial concerns—their breadth of view and keenness of outlook; their tireless efforts and unfailing perseverance in attacking problems needing years for solution, and for which no early return for the large expenditure involved could be anticipated. Nothing, we are told, appeared to have struck the Mission more than the lavish monetary outlay on laboratories, libraries, and technical staffs. As an example, an account is given of the leading features of the great Bayer works at Leverkusen, one of the most highly organised of the Rhineland factories. We have also a brief statement describing the rapid development of power stations in the Rhine district, especially during the war; and some account of the working of the *Interessen Gemeinschaft* (I.G.), by which the leading chemical firms co-operate so as to secure community of interests. But limits of space preclude any detailed account of the several matters of interest covered by the report. Enough, however, has been written to indicate its importance. Whilst we cannot wholly subscribe to every statement of the writer of the summary, who has been allowed, possibly, too free a hand in interpreting the findings of the report, we can at least testify that he has the courage of his convictions and little hesitation in giving utterance to them.

Man: Past and Present.

Man: Past and Present. By A. H. Keane. Revised, and largely re-written, by A. Hingston Quiggin and A. C. Haddon. Pp. xi+582+xvi plates. (Cambridge: At the University Press, 1920.) Price 36*s*. net.

IT is scarcely necessary to extol the virtues of the late Prof. A. H. Keane's invaluable compilation of data relating to the races of mankind and their customs (see NATURE, June 8, 1899, p. 121), for it has been the *vade mecum* of almost every working ethnologist for more than twenty years. If the authors of the new edition had a task of exceptional difficulty in practically re-writing a work of so encyclopædic a nature they also had a great opportunity. Moreover, Mrs. Hingston Quiggin and Dr. Haddon had exceptional, if not unique, qualifications for making the most of their chance. But they have contented themselves with pouring their new wine into Keane's old bottles. Even so glaring an anachronism as Keane's classification of the races of mankind and the use of the unpardonable term "Caucasian," with many of its unfortunate implications, have been retained. They have made a digest of the modern literature of ethnology that will be extremely useful to the expert, who knows what to select and what to reject, but utterly bewildering to the student and the general reader, who expect some sort of consistency and some leading idea to bind together such vast masses of data as are presented to them in this book. Instead of this they will find an excellent series of extracts from a host of authors without any serious attempt to create a consistent story or to explain the wide discrepancies in their interpretations of the facts.

Although the authors direct attention (pp. 351–53) to the fact that fatal objections have been made to the fashionable speculation of the independent origin of cultures, throughout the rest of the book they ignore this warning and adopt an extreme attitude in flagrant opposition to the doctrine of diffusion. Take, for example, the dogmatic statement on p. 23:—"In fact, we know for certain that such an independent Copper Age was developed not only in the region of the Great Lakes of North America, but also amongst the Bantu peoples of Katanga and other parts of Central Africa": the researches of one of Dr. Haddon's own pupils, Mr. W. J. Perry, have shown this claim to be totally unfounded. Copper was not used in either of these places until immigrants who had already become acquainted with the economic value of the metal elsewhere had made their way into these territories and discovered the new sources of supply.

This sort of fallacy runs through the whole book, and will be a repeated source of confusion to the thoughtful student. What, for example, will he think of the statement on p. 465: "The idea of an independent evolution of Western [European] culture is steadily gaining ground," after reading a hundred pages earlier that the opposite tendency is now strongly asserting itself?

The late Prof. Keane was a strong supporter of the speculation of the independent origin of culture, and at times became almost fanatical in giving expression to his devotion to the fashionable craze. But the authors of the present edition, in spite of their pretence of impartiality, go further than the original author. The latter was not always consistent. While he poured scorn upon the whole theory of the diffusion of culture and quoted with child-like gusto the worst extravagances of Brinton's and J. W. Powell's denials of the possibility of such a spread of civilisation as everyone knows to be happening at the present time, he frankly and fully adopted it as the explanation of the ancient Rhodesian monuments at Zimbabwe. But the authors of the present edition reject Keane's solution of the Zimbabwe problem, and adopt Dr. Randall-MacIver's discredited speculations. Thus we are told that "exploration in 1905 dispelled the romance hitherto connected with the 'temples' and produced evidence to show that they were not earlier in date than the fourteenth or fifteenth centuries [*sic*], and were of native construction" (p. 89). Dr. Haddon does not enlighten his readers as to how the discovery of a piece of medieval *Chinese* pottery in one of the altogether subsidiary buildings at Zimbabwe can prove that the great buildings were built by *negroes* not earlier than the fourteenth century. The discovery of a piece of willow-pattern plate in the foundation of a house at, say, Bristol would not prove that the Roman buildings at Bath were erected by Englishmen in the nineteenth century! Yet this is the sort of argument which is naïvely borrowed by Dr. Haddon, who is well aware of the multitude of data entirely fatal to it.

The authors, in fact, seem to have accepted without discrimination anything that has recently appeared in print, and not tested it in the light of their own knowledge. Thus they have reproduced without comment or criticism some of the least excusable fallacies of current ethnological literature. For example, in their discussion of the origin of Chinese civilisation (p. 207) they confuse race and culture. They are giving the reasons for not deriving the *people* of China from south-western Asia, when they are really discussing the origin of Chinese *civilisation*. Writers

who had compiled the vast mass of data in this book should have had no hesitation in dismissing once for all any suggestion that "the present inhabitants of China are late intruders of south-western Asia" (p. 207). At the same time, they should not have been blind to the fact that there is ample evidence to demonstrate how most of the Chinese customs and beliefs were inspired by events that were occurring in Elam, Sumer, and Turkestan early in the third millennium, the influence of which was gradually transmitted to Shensi by prospectors searching for gold, fresh-water pearls, and jade in the heart of Asia.

But the writers have not understood the meaning of these facts. Nowhere in the book is there so much confusion as in the sections relating to Turkestan. On p. 257 they qualify their acceptance of Prof. Ellsworth Huntington's views by quoting Dr. Peisker's wise warning that "[change of] climate was not the sole or even the main factor" in causing the desolation of Turkestan and Central Asia; yet on p. 263 they seem to forget the need for caution, and attempt to explain the origin of Sumerian civilisation as one of the results of a period of drought in Central Asia. To those who are acquainted with the scientific results of M. de Morgan's "Mission en Perse" it will come as a surprise to be told that "recent archæological discoveries [by which the writers refer to Huntington's desiccation hypothesis] make Sumerian origins a little clearer"! On the contrary, M. Edmond Pottier's report on the earliest painted pottery found by M. de Morgan in Susa proves conclusively that the earliest ceramic ware from Turkestan was directly inspired by Elam. So far from the origin of Sumerian civilisation being explained by discoveries in Turkestan, we now know that the culture of the latter area was derived from the neighbourhood of the Persian Gulf.

These examples serve to illustrate the weakness of the book. While making an encyclopædic compilation of extracts from the most recent writers, the authors have made little attempt to assimilate and co-ordinate the collection of facts. Nor has any attempt been made to link together the data by means of any general idea or principle. The book has been compiled at a time when the facts of ethnology are being illuminated by the brilliant light of a new theory which explains how and why the elements of our common civilisation were spread abroad in ancient times by prospectors searching for pearls and the precious metals. This revolutionary idea in ethnology was propounded by one of Dr. Haddon's pupils, Mr. W. J. Perry. But it is clear from this book that Dr. Haddon has utterly failed to appreciate the new vision in ethnology which his own school has effected.

There is no reference to the Talgai skull, and Sir Baldwin Spencer's assumption that the Tasmanians must have crossed Bass Strait on dry land is accepted without comment. Why people whose ancestors had already crossed Wallace's line by boat could not also have ferried across Bass Strait is not apparent!

The lack of maps and diagrams is a serious defect, and many of the illustrations at the end of the book are far from satisfactory. I think it unfortunate that a book of this character should have been issued at the present moment, for it will give the world outside Cambridge an altogether misleading idea of the nature and quality of the excellent training which the Cambridge School of Anthropology is now providing.

G. ELLIOT SMITH.

Critical Mathematics.

Les Principes de l'Analyse Mathématique: Exposé Historique et Critique. By Prof. Pierre Boutroux. Tome second. Pp. iv+512. (Paris: Librairie Scientifique A. Hermann et Fils, 1919.) Price 20 francs.

THIS second volume of Prof. Boutroux's work contains the outlines of analytical plane and solid geometry, projective geometry, the theory of ordinary complex quantities, infinite series and products, infinitesimal calculus, analytical functions. There are also very brief notices of determinants, groups, aggregates, vectors, elliptic, abelian and fuchsian functions.

On the whole, the volume may be described as a varied and stimulating course likely to interest a competent university student and induce him to follow up one or more of the numerous branches of mathematics to which his attention is directed. Owing to the variety of topics introduced, much of the didactic part of the course is very fragmentary; at the same time, it is elegant and suggestive.

To the teacher, the most interesting part of the volume is the critical and historical matter. The historical sections seem to be admirable in every way—judicious, impartial, and in proper perspective and proportion. Among other things, attention is directed to Fermat's contributions to analytical geometry, some of which, in a measure, anticipated Descartes. At the same time, it is pointed out that, whereas Descartes had in view the ousting of pure geometry by analysis, Fermat, like Newton, remained faithful to the old methods, regarding analysis mainly as an auxiliary. Prof.

Boutroux properly directs attention to the fact that much of Apollonius's "Conics" is essentially analytical, though, of course, there is no algebra, strictly so called. In the sections on function-theory, due reference is made to Méray, who shares in great measure with Weierstrass the credit of laying the foundations of a sound theory of analytical functions. It is fortunate that the great similarity of the work of these two mathematicians did not give rise to bitter polemic; there was at least as much material for it as in the famous Newton-Leibniz controversy.

The author's critical remarks, we fancy, will not meet with such unqualified acceptance. To take one example, he says of Peano's symbolism: "Unfortunately, it is not everyone who can read with facility these combinations of signs, which are often grotesque and repulsive, and unaccompanied by a single word of the vulgar tongue. Moreover, M. Peano's symbolism cannot claim to have made any contribution to the progress of mathematics; it remains a remarkable method of scientific shorthand." As a criticism of the work of Peano and his school, this is distinctly unfair. Anyone who has the patience to become moderately familiar with the notation is bound, we believe, to admit that the alternative is either to produce a text full of ambiguities and tacit assumptions, or else one of intolerable prolixity. The present reviewer has come to this conclusion with very great reluctance; even the Cambridge Press has not succeeded in making the "Principia Mathematica" attractive to the eye; and it is to be feared that the first impression it is likely to produce is that it is the work of a drunken compositor. Probably its use will be mainly, if not wholly, confined to the logical foundations of mathematics; for this purpose we think its value is indisputable. There are other controversial statements scattered about the text; they all deserve careful attention, even if the reader is inclined to disagree with them.

There is one point, of frequent occurrence, against which we feel bound to protest. Prof. Boutroux repeatedly says that such an equation as $x^2+y^2=0$ represents *a point*. This is absolutely untrue; it may be said to represent a point-circle (circle of zero radius), or a pair of isotropic lines, according as we exclude or include complex elements. But no single equation in point-co-ordinates can represent a point; moreover, it is fatal to ignore the degree of the equation. Oddly enough, Halphen makes the same mistake in his memoir on characteristics; he repeatedly gives the name of "a single line" to what is, as a degenerate *quadratic* locus, a double line with two special points (or, exceptionally, one special double point) upon it. Fortunately, this does not affect Halphen's conclusions, the reason (apparently) being that he discusses point-equations and line-equations simultaneously.

We hope that this work will have a good circulation in England; its virtues are precisely those in which our text-books still leave something to be desired: elegance, breadth of view, choice of topics, and regard to historical perspective.

G. B. M.

The Proteins.

The Physical Chemistry of the Proteins. By Prof. T. Brailsford Robertson. Pp. xv+483. (London: Longmans, Green, and Co., 1918.) Price 25s. net.

THIS is not a new book. It first appeared in the form of an edition in German published at Dresden in 1912. The second edition, in English, has, however, been so completely re-written as to make it practically a new account of the subject.

There are four parts, of which the first deals with the mode of preparation and estimation and the chemical constitution of proteins; the second with their electro-chemistry; the third with the physical properties of their solutions, such as viscosity, refractive indices, etc.; and the last with what the author calls the chemical dynamics of protein systems, by which, broadly, he means their reactions with catalysts. It will be seen that a complete survey of the subject has been attempted, and it may be said at once that, as an introduction to the literature, already extensive, the book can be commended.

It is now agreed that the proteins are chemically a homogeneous group the molecules of which are built up by the synthesis of amino-acids. The size of the molecules so formed is still open to doubt. Emil Fischer, than whom no one could speak with more authority, refused to accept the molecular weights of 15,000 to 20,000 commonly ascribed to native proteins. The molecular weight, indeed, varies widely from the 16,000 of hæmoglobin, or the 17,000 of edestin, to the values reckoned in hundreds of the polypeptides. It certainly lies in the thousands for native proteins, and is large enough to upset the simpler stoichiometrical relations.

Consider, for example, the reaction with acids and alkalis. Proteins, like amino-acids, are amphoteric—that is to say, they will form salts with either an acid or a base—but, according to the author, when their combining equivalents are determined by known methods, their combining capacity is found to be much in excess of the

possible number of terminal —OH or —COOH groups.

For example, casein, according to the author, behaves as a 16-base acid. To provide sixteen terminal carboxyl groups, the molecule would have to be either a branched chain, or chains radiating from a centre where carbon atoms are directly linked one to another. Such a molecular structure, however, would render the decomposition of the casein molecule on hydrolysis into its constituent amino-acids unintelligible.

Moreover, the form of the molecule of the polypeptides which have been prepared synthetically is not open to doubt, and it is not radial, but a chain, the constituent amino-acids being joined end to end.

The amino-acids of the chain are united by a CONH linkage, which may have a keto- or enol-form, and it is here the author supposes that the reaction with acids or bases takes place.

Consider the simplest case—that of a dipeptide. If combination with an acid or a base takes place at the middle of the chain where the CONH linkage is situated, and the salt ionises in solution, the dipeptide molecule will form two protein ions. Salts of proteins, therefore, should yield, not a protein ion and a simple ion such as $Na^{\cdot}$ or Cl', but two oppositely charged protein ions.

This hypothesis is the central feature of the book, which, indeed, is devoted to following out its consequences. Its validity has been challenged, but, whether true or false, no worker or student will be the worse for learning what it leads to.

Obviously, one consequence is that when a solution of the salt of a protein is electrolysed, the protein should migrate to both cathode and anode. But, as a matter of fact, as Hardy's observations show, the protein migrates only in one direction and in quite a normal way. The author recognises this difficulty and attempts to meet it, but, owing to a slip in the reasoning, his argument would appear to upset his own theory.

Science and Engineering.

Engineering Education: Essays for English. Selected and edited by Prof. Ray Palmer Baker. Pp. ix+185. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1919.) Price 6s. net.

THIS is an interesting small book containing addresses or portions of addresses by distinguished professors and consulting engineers bearing on the importance of a knowledge of science to engineers. Dr. Steinmetz, of the General Electric Co., urges the need of a broad culture, and especially of the study of Greek and Latin classics, for engineers. Prof. McClenahan, of Princeton University, advocates a three- or four-year course of literary and scientific studies, followed by a two-year technical course. Mr. J. L. Harrington, a well-known engineer and bridge designer, points out the necessity for a thorough knowledge of English.

"It is notorious that a technist is rarely a good business man. This is partly because of the exaggerated importance he gives to technical matters, but very largely because his thought is clumsily expressed and awkwardly ordered."

Mr. Harrington remarks on the frequent obscurity of specifications, and tells of a contractor who never completed a contract without a lawsuit to determine the meaning of a specification, and who had never lost a lawsuit. Sir W. H. White and Prof. Ranum, of Cornell University, write on the value of mathematics. There are addresses on chemistry and physics, and a distinguished consulting engineer, the inventor of the obelisk dam at Niagara, built on end on the shore and then toppled into the river, writes on the importance of imagination.

It strikes a reader that these addresses, each advocating the claim of some one branch of science, interesting as they are, would have been more useful if there had been a recognition of the distinction between what should be included in the school course preceding the technical course, in the technical course itself necessarily restricted, and what extra academic self-education should be expected to accompany and follow it. It may be surmised that engineering students in the United States do not enter on the technical course as well prepared as they should be, and this is certainly to some extent the case here. But preachers on education might remember what Stevenson says of Sainte-Beuve, that he regarded all experience as a single great book in which to study for a few years before we go hence; and it seemed all one to him whether you read in chap. xx., which is the differential calculus, or in chap. xxxix., which is hearing the band play in the gardens.

There is also an admirable address by Sir J. J. Thomson, delivered before the Junior Institution of Engineers, on the relation of pure science to engineering. Sir Joseph remarks that the scientific spirit has not diffused through and influenced the bulk of our industries to the extent it has done in one or two other countries. He traces the evil to the fault of the secondary school, the inefficiency of which causes the technical course to be overloaded.

"The curriculum is founded on the truly British idea that our boys are not expected to learn any-

thing at school. Most of the work in the courses for students in their first year, and some of that in the second, in all the engineering schools with which I am acquainted, is of a kind that a boy might well be expected to do at school. There is no reason why a boy of eighteen, of the mental calibre which would justify his becoming an engineer, should not have a good working knowledge of the calculus and the elementary parts of differential equations, and have read a considerable portion of dynamics. This could, I am convinced, be done without undue specialisation, and without depriving the boy of the literary training which is essential, if he is to keep his sympathies wide and his mind receptive."

W. C. U.

Health and the Teacher.

A Text-book of Hygiene for Training Colleges. By Margaret Avery. Pp. xv+324. (London: Methuen and Co., Ltd., 1919.) Price 7*s.* 6*d.* net.

THIS book is intended to cover the subject-matter of the Board of Education Certificate Examination for Training Colleges in England. It includes the usual anatomico-physiological "properties" long familiar in books of this order since the days of Huxley's "Physiology": elementary ideas about structure of tissues, the skeleton, the muscular system, the circulatory system, the digestive system, etc. But the exposition is kept well within the technicalities suited to the students concerned. There are chapters on food, clothing, cleanliness, mental dullness and deficiency, fatigue, infectious diseases, temperance, school building, medical inspection and treatment, special schools, welfare of infants and young children, legislation affecting school children, and eugenics.

This is a very large programme for so small a book, but the expositions, which, incidentally, retain a good deal of the somewhat loose notes-for-lecture style, are, on the whole, relevant and practical. The author has kept close touch with official memoranda, reports, and standard books. The result is that the volume, all through, contains good informational material which has obviously stood the test of experience in the class-room.

It is difficult to say how much medical information proper should be included in a book like this, but to untrained lay persons it is of no value to state that, in anæmia, "a little iron often has excellent results" (p. 42). Again, as to the cause of rickets, something more is wanted than that "the cause is wrong food, chiefly lack of fat, a lack existing in all patent foods" (p. 88). This kind of information may fulfil the terms of a syllabus, but it is of no value whatever to the student, though, usually, in a practical curriculum, there are many opportunities of supplementing these generalities by demonstrations of cases.

The chapter on "First Aid" relies on accepted instructions, but Schäfer's method for recovery from drowning should have a place. The chapters on legislation affecting children and on eugenics are judiciously proportioned, but the remarks on the causes of pauperism as implying "a want of grit and independence" (p. 305), and on feeble-mindedness and heredity, show that the author has accepted somewhat too uncritically the theoretical deductions of "experts." The book will, however, serve as a good text-book for the practical teacher.

Our Bookshelf.

The Mineralogy of the Rarer Metals: A Handbook for Prospectors. By Edward Cahen and William Ord Wootton. With a foreword by F. W. Harbord. Second edition, revised by Edward Cahen. Pp. xxxii+246. (London: Charles Griffin and Co., Ltd., 1920.) Price 10*s.* 6*d.*

THIS book is neatly bound, and is of handy size for the pocket. The mineral descriptions are conveniently treated in a general way in the alphabetical order of the metals. The alkali metals come first; then follow beryllium, cerium, and so on to zirconium. Under each metal the properties, preparation, industrial application, and ores are first considered; following this an account of the chemical methods for its detection, and a list of the minerals containing the metal, are given. Much care appears to have been taken in describing the chemical and physical character of the minerals and the tests available for purposes of identification. Separate sections at the end of the book deal with the geographical distribution of rare metals and methods of analysis.

To the critical reader of the book many of its features suggest questions and scope for improvement. Is it permissible to regard titanium as a rare metal? Ilmenite is certainly not a rare mineral, and it is incorrect to refer to this mineral as "a chief constituent of monazite from Travancore and Ceylon" (p. 130). It would be more correct to say that the chief producer of rutile is Virginia, U.S.A., than to imply, as the author does, that the chief producer is Norway (p. 131). Under tungsten no mention is made of the wolframite deposits in China, which has recently been the leading producer (p. 141). Zircon is mentioned as occurring in "Scotland and Ireland," but no mention is made of its universal distribution in sands and gravels such as those of Hampstead Heath (pp. 182, 189).

The section dealing with geographical distribution has been revised, but it might with advantage be amplified to include such countries as Spain,

Portugal, and France, where there are many occurrences of greater importance than some that receive mention in this book. T. C.

A Text-book on Machine Drawing for Electrical Engineers. By E. Blythe. (The Cambridge Technical Series.) Pp. vii+81. (Cambridge: At the University Press, 1920.) Price 20*s.* net.

ALL teachers of electrical engineering are aware of the need for a text-book on the drawing and construction of electrical apparatus. This attempt, however, to supply the need is disappointing. Apparently the author intends the book to serve for a complete course of machine drawing for electrical students, for he commences with the laws of projection and gives several very simple examples in illustration of them. He proceeds then to fastenings, cable sockets, junction-boxes, switches, and dynamos. The subject-matter is confined entirely to such apparatus as is found in small continuous-current power stations (but instruments are not included); consequently the alternator, induction motor, oil-switch, and other important pieces of electrical apparatus are notably absent. Several complete plates are devoted to non-dimensioned sketches showing types of apparatus, *e.g.* one on brush-holders; a few such examples are undoubtedly useful for practice in sketching, but here too much space is occupied in this way. The drawings are clear and very well arranged, but the descriptive matter is unnecessarily prolix. The examples given do not always represent good practice; for instance, in several places a single-piece armature disc is shown with a dove-tailed key, while a bearing is shown on p. 73 which would be destroyed by a little end-thrust. The book is well got up and has been prepared carefully; but the ground covered is insufficient— at the price.

Mathematics for Engineers. Part ii. By W. N. Rose. (The Directly Useful Technical Series.) Pp. xiv+419. (London: Chapman and Hall, Ltd., 1920.) Price 13*s.* 6*d.* net.

PART ii. of this book is devoted principally to the differential and integral calculus, and includes chapters on spherical trigonometry and mathematical probability. The book is intended for engineers, most of whom are not called upon in their profession to show capacity for high mathematical flights, but are expected to comprehend clearly such fundamental principles as enter into their work, and to be ready successfully to apply them to practical problems. Examining the book from this point of view, we believe that it will find favour with most engineers and students of engineering. If we include also the matter comprised in Part i. the volumes contain practically everything in the way of mathematical principles which the engineer is likely to require. The treatment is clear and of a kind which appeals to engineers, and a very large number of practical applications are given. Many of these are fully worked out to the arithmetical result, and there are very few which can be said to be of an academical nature only. These examples cover a wide field, having been drawn from all branches of engineeering, and represent a large amount of labour for which engineers will be grateful. We can heartily recommend this volume, as well as its predecessor, to all students of engineering.

The Manufacture of Intermediate Products for Dyes. By Dr. J. C. Cain. Second edition. Pp. xi+273. (London: Macmillan and Co., Ltd., 1919.) Price 10*s.* net.

PROBABLY no one in this country is more competent to write on intermediate products than Dr. Cain, and the fact that a new edition of this book has been called for within a year is the best testimony to its success. The opportunity has been taken to improve certain sections and to incorporate new work, most of which, it is of interest to note, originates now in America. It is gradually being realised that intermediates are the crux of the dye situation, and the wisdom of the policy adopted in this direction by British Dyes, Ltd., in building their new factory at Huddersfield is becoming apparent. Given the intermediates, the manufacture of the several dyes is usually a fairly straightforward problem, but there is still much leeway to make up in connection with intermediates, which will require the most ample resources, alike in capital, plant, and technical experience. This will take considerable time to fructify, and some form of closer co-operation with the heavy chemical trade would appear most desirable.

The British colour industry is receiving some adverse criticism from the users of the rarer colours for which the demand, at the most, is but small, but it has a more important task at the moment than to fritter away its energies in making these colours. The colour industry is based on intermediates; it is the manufacture of these by the best methods, with the largest yields, and of satisfactory purity which must be studied in the laboratory and in the works. This is being done, and Dr. Cain, through his book, in which the available information is clearly presented, is helping to do it.

Solutions of the Examples in a Treatise on Differential Equations. By Prof. A. R. Forsyth. Pp. 249. (London: Macmillan and Co., Ltd., 1918.) Price 10*s.* net.

EVEN from the point of view of an undergraduate, the subject of differential equations is very different from what it was fifty years ago. But in a large and miscellaneous collection of examples like this there are a number of survivals which remind us of De Morgan's application of the proverb: "Those that hide know where to find." Teachers and solitary students (if such there be nowadays) will be grateful to Prof. Forsyth for providing them with a key. It is one more example of the author's untiring industry and, so far as we have tested it, of his accuracy in details of analysis. M.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Theories of Atomic Structure.

IN a letter to NATURE (March 11, p. 41) S. C. Bradford stated: "The great objection to Langmuir's theory of atomic structure is the difficulty of accepting his hypothesis of stationary electrons." The cases cited are all discussed in G. N. Lewis's paper, "The Atom and the Molecule" (Journ. Amer. Chem. Soc., xxxviii., p. 762, April, 1916), so it is scarcely fair to Lewis to refer to the theory as "Langmuir's theory."

Although Lewis frankly implied that the electrons in atoms are stationary, his theory of valency did not depend upon such an assumption. The chemical data give information in regard to the geometry of atoms, and, in particular, tell us of the kinds of symmetry which they possess. From the chemical point of view it is at present a matter of comparative indifference what the motions of the electrons may be so long as they conform to the required conditions of symmetry. For this reason I was careful to state in my first paper (Journ. Franklin Inst., clxxxvii., p. 359, March, 1919, and Journ. Amer. Chem. Soc., xli., p. 932, 1919) that "the electrons in atoms are either stationary *or rotate, revolve, or oscillate about definite positions in the atom.*" It was, perhaps, not sufficiently emphasised that the positions of the electrons shown in the diagrams may be regarded as the centres of their orbits.

It is sometimes thought that the success of Bohr's theory furnishes reason for believing that all the electrons in atoms are rotating in coplanar orbits about the nucleus. There is little justification for this opinion. The remarkable results yielded by Bohr's theory, particularly in the hands of Sommerfeld, for the case of the hydrogen atom and the helium ion seem to prove beyond question that in an atom containing only one electron this electron actually revolves in a circular or elliptical orbit about the nucleus. Although Bohr's theory has had some applications to other atoms, these are, for the most part, of a very general nature, such as those which relate to the combination principle. The theory does not give a satisfactory model even for such simple structures as the hydrogen molecule or helium atom (see, for example, Sommerfeld's recent book, "Atombau und Spectrallinien").

From the chemical point of view Bohr's theory is wholly unsatisfactory when applied to atoms containing more than one electron. Thus, according to Bohr's calculations (*Phil. Mag.*, xxvi., p. 492, 1913), a lithium nucleus surrounded by three equidistant electrons should have less potential energy (and, therefore, greater stability) than one in which one electron is further from the nucleus than the other two. Bohr's theory thus gives no reason for the contrast between the properties of lithium and helium.

The two theories are not mutually incompatible if we consider that, in general, the electrons do not revolve about the nucleus, but about definite positions symmetrically distributed in three dimensions with respect to the nucleus. It is interesting to note that Born and Landé (*Verh. deut. physik. Ges.*, xx., pp. 210, 230, 1918), starting out from Bohr's theory and without knowledge of Lewis's work, were led to the theory of the cubical atom by a study of the compressibilities of the alkali halides. They conclude that the electron orbits do not lie in a plane, but are arranged in space with cubic symmetry. Sommerfeld in his book suggests that this conception may help to solve some of the outstanding difficulties, and evidently does not consider it inconsistent with Bohr's theory.

In the case of atoms which do not share electrons with other atoms, it is logical to assume that each electron in the outer shell has its own orbit. Thus the atoms Ne, Na^+, Mg^{++}, F^-, and the S atom in SF_6 should have cubic symmetry, the eight outer electrons revolving about positions located at the corners of a cube. But where a pair of electrons is held in common between two atoms, the chemical evidence indicates that the pair acts as a unit. When an atom shares four pairs of electrons with its neighbours, it thus has tetrahedral rather than cubic symmetry. So far as the chemical evidence is concerned, it would be satisfactory to adopt Bohr's model for the hydrogen molecule to represent the pair of electrons which constitutes the chemical bond. We may thus picture the chemical bond as a pair of electrons revolving in a single orbit about the line connecting the centres of the two atoms.

Bohr in his 1913 paper (*Phil. Mag.*, xxvi., p. 874) states: "The configuration suggested by the theory for a molecule of CH_4 is of the ordinary tetrahedron type; the carbon nucleus surrounded by a very small ring of two electrons being situated in the centre, and a hydrogen nucleus in every corner. The chemical bonds are represented by four rings of two electrons each rotating round the lines connecting the centre and the corners." This structure is quite consistent with the octet theory. Bohr did not, in general, identify a pair of electrons with a valency bond.

When we consider, however, that Bohr's theory in its present form does not furnish an explanation of the stability of the pair of electrons in the helium atom and in the bond between atoms, it is evident that the model described above can scarcely be regarded as satisfactory. It seems as though some factor of vital importance is still missing in Bohr's theory. The chemical data suggest that the ultimate theory will be extremely simple, but perhaps more radical than anything yet proposed.

I am in full agreement with the views put forward by Dr. H. S. Allen in NATURE for March 18, p. 71.

IRVING LANGMUIR.

Research Laboratory, General Electric Co., Schenectady, New York, April 12.

Decimal Coinage.

IN NATURE of April 1, p. 145, reference is made to the unfavourable report of the Royal Commission appointed to inquire into the above subject. It would appear from a close study of the findings of the Commission that the failure to solve this century-old problem was due more to differences between the advocates than to opposition to the principle.

Although fifteen of the twenty Commissioners would prefer to decimalise the existing £ sterling rather than to create a new monetary unit equal to 100 halfpence, it is significant that only four of them could agree that the advantages to be secured by the decimalisation of the £ would outweigh the inconvenience arising from the change. This is tantamount to an admission that the method of dealing with the penny difficulty as proposed in Lord Southwark's Bill (£—mil) was unduly complicated. (No exact equivalent of the penny was provided, the choice of a 4-mil and 5-mil piece being alternatively offered.)

Retaining the £ as the unit, there are three possible values for the penny, viz.:

4 mils = the present penny less 4 per cent.
5 mils = the present penny *plus* 20 per cent.
$4\frac{1}{6}$ mils = the present penny exactly.

The claims of these denominations may be summed up as follows:

The 4-mil Penny.—As the denomination 4 represents neither a decimal multiple of 1 nor a binary division of 10, a 4-*mil* coin could have no permanent place in any decimal coinage system. As a transitional value it would also be unattractive, because it would still further reduce the purchasing power of the penny at a time when an increase is needed, and its temporary adoption would involve two adjustments of existing pennyworths, thus doubling, instead of removing, the difficulty. For these and other reasons a 4-mil penny may be safely dismissed from our consideration.

The 5-mil Penny.—There are at least four good reasons in its favour, viz.:

(1) In a decimal coinage system prices are normally arranged in steps of 5, *e.g.* 5, 10, 15, 20, 25, etc., and the value of 5 mils would fall conveniently between that of the unduly high 5 American cents and the unnecessarily low 5 centimes of the Latin Union.

(2) The reduction of the present high prices would be hastened by the provision of a penny of this value. The price of a pre-war pennyworth, now sold at three-halfpence, could obviously be reduced to 5 mils long before it could be restored, if ever, to the original penny.

(3) The prevailing shortage of copper coins would be relieved by thus increasing the token values of all the penny and halfpenny coins now in circulation. Two copper coins are now employed in countless transactions where formerly one sufficed, and this fact alone, quite apart from decimalisation, demands a penny of higher value.

(4) The simple relationship of 10 pence to the shilling would be readily grasped by the uneducated, and the deservedly popular single-coin payments would be restored. Retail shopkeepers could, if so desired, continue to keep their accounts in £ *s. d.* instead of £ *f. m.*, the $2\frac{1}{2}$, 5, 10, and 25 mil coins being in that case entered as $\frac{1}{2}$, 1, 2, and 5 pence, all the higher value coins retaining their present descriptions as 1, 2, 5, and 10 shillings respectively.

Note.—The majority Commissioners apparently feared that 5 mils would always be charged in place of the present penny. If they had said in place of the present three-halfpence, they would have been just as near the truth, which possibly lies between these two views. Probably everyone would now be very glad to pay 5 mils for a pre-war pennyworth of anything—the trouble is we are charged three-halfpence or more. When introducing this year's Budget the Chancellor of the Exchequer (referring to his proposal to raise the receipt duties from 1*d.* to 2*d.*) said: "This change is no more than reflecting the altered value of the penny."

The $4\frac{1}{6}$-mil Penny.—If there are insuperable difficulties in the way of raising the values of the existing penny and halfpenny coins to make them serve as tokens for 5 mils and $2\frac{1}{2}$ mils respectively, they could remain in circulation at their present values side by side with new 5-mil nickel coins, in which event their values in mils could be expressed as 4-2 and 2-1 respectively, the latter figure representing twelfths of a mil. (These expressions would be no worse than our present use of 4/2 to represent four shillings and two-twelfths.)

The present penny could thus be preserved indefinitely for the continued exact payment of all statutory pennyworths, but the competition of the smaller, lighter, and cleaner 5-mil nickel coin, representing a value in closer harmony with present-day needs, would rapidly drive the bronze penny out of popular favour for the countless single-coin payments of daily life. In concluding that this method might involve the dual circulation of pence and mils "for seventy-five years or more," the majority Commissioners have unwarrantably assumed that no steps would be taken by the established "penny" interests, such as insurance and tramway authorities, etc., to bring themselves into line with the new mil system, whereas many of these interests are already agitating for legislative authority to abandon the penny basis, which has proved inadequate to cover operating costs. Many of the old fixed penny charges, such as the penny stamp, penny-a-mile, etc., have already disappeared, and the retention of the coin itself is no longer a matter of vital importance.

The £ sterling could thus be decimalised either without altering the penny or by raising its value to 5 mils (either instantaneously or gradually), and so securing substantial benefits over and above those normally arising from decimalisation.

Having very truly said: "It is necessary to distinguish between the coins in circulation and the reckoning of money of account," and having properly referred to the human habit of halving quantities, the Commissioners failed to realise that it is quite practicable to combine the advantages of decimal accounts and binary coins. Such a composite scheme would provide decimal multiples and binary divisions thus:

Coins	In accounts			Equivalent		
	£	*f.*	*m.*	£	*s.*	*d.*
Gold or Note:						
Pound	1	0	00	1	0	0
Half-pound		5	00		10	0
Quarter-pound (crown)		2	50		5	0
Silver:						
Florin		1	00		2	0
Half-florin (shilling)			50		1	0
Quarter-florin			25			6
Nickel:						
Dime (10-mil piece)			10			2·4
Bronze:						
Half-dime (penny)			5			1·2
Quarter-dime (halfpenny) ...			$2\frac{1}{2}$			0·6
Mil			1			0·24

The above proposal achieves the complete decimalisation of the £ by means of a smaller number of coins and in a simpler manner than by the method described in Lord Southwark's Bill. No decimal point would be needed, the number of figures would be reduced, and no new coins would be immediately required.

HARRY ALLCOCK.

Trafford Park, Manchester, April 21.

International Council for Fishery Investigations.

As the writer of the article on the above subject in NATURE of March 18, I should be disposed to allow Prof. McIntosh's letter in the issue of April 8 based on it to pass without comment if that letter had not been quoted extensively elsewhere. I merely remark that the professor's claim to maintain the same position as he took up in his published criticisms in 1902 and 1903 is fully substantiated. I see no reference in my article to the Moray Firth, which, indeed, had nothing to do with the International Council, and which I must leave Prof. McIntosh to settle with his fishery colleagues in Scotland. His criticism of the representatives of France is out of place, in that representatives of all countries are appointed by their Governments.

Prof. McIntosh confuses the programme adopted with the general discussion which took place first. Commodore Drechsel and others spoke of "the closure of the greater part of the North Sea as the most gigantic scientific experiment ever made [will

any scientific man contest this view?] in respect to the closure of areas." This is stated by Prof. McIntosh to be the first item in the scheme of investigations, whereas no such general scientific investigation is recommended. Whether or not the fisheries of the North Sea will be permanently altered by the closure consequent on the war no one knows, but certainly trawlers have been experiencing the immediate benefit of the closure since the armistice. The extent to which the North Sea is covered by the operations of trawlers is evidently not understood. The work of Masterman, Heincke, and others results in the estimate that 1500 million plaice of more than 12 cm. live in the North Sea, of which one-third are caught annually, 200 million being put on the market and 300 million being destroyed in the process of catching.

Again, Prof. McIntosh refers to one part only of the proposal for the protection of plaice, viz. that by a size limit, whereas the permanent closure of certain areas "to provide a reserve from which the young plaice might spread so as to restock the open grounds" is definitely mentioned in my article. Prof. McIntosh apparently does not realise that the representatives of at least three of the four countries that are particularly interested in the plaice stock of the North Sea are convinced that the evidence shows that the plaice stock is, under normal conditions, being so seriously depleted by man that international legislative action is essential. In view of such action, the proposed year's intensive plaice investigation is fully justified. We wonder whether Prof. McIntosh has examined the statistics that have been published in respect to the plaice and other flat-fishes year by year?

Prof. McIntosh scoffs at the basal researches on the physico-chemical conditions of sea-water in respect to the life in the sea as likely to be of any importance. He selects in particular "vitamines." His remarks should be read in connection with my paragraph to which he refers. It is self-evident that even the largest quantity of food can be of no use to a living animal unless that animal has the requisite power to build up that food into its own living matter. The understanding of this at every age of the animals in question—and of animal life in general—is the object of these researches. There seems to be no such thing as "pure sea-water" without "vitamines."

It may not be generally known that an almost judicial committee appointed by the Development Commission is at present sitting on the question of fishery research. There is no member of that committee employed in fishery research, and, equally, there is no member of the committee who is incapable, by training or otherwise, of understanding any parts of the problems to be investigated. The report of that committee should shortly be issued. It will doubtless be an authoritative pronouncement upon the whole question as to the utility or non-utility of fishery investigations as proposed by the International Council and as undertaken by the Fishery Departments of England, Scotland, and Ireland.

The Plumage Bill and Bird Protection.

NATURE is doing a service to science, as well as to art, in having opened its pages to the discussion of the Plumage (Prohibition) Bill. For in the end the Bill should be drafted in harmony with the scientific facts concerning the bird-life it is designed to protect, and also with due regard for the æsthetic and decorative needs of mankind. There is one aspect of the subject which has hitherto been only lightly touched upon, but which, if unfettered, is sure to become of great importance in the future, namely, the domestication of plumage birds. Impressed with the success of its ostrich industry, South Africa has for some time turned its attention to the possibility of the domestication of other plumage birds. Experiments have already demonstrated that the marabou stork can be controlled in captivity and, in all probability, induced to breed. Attention has also been directed to the gregarious weaver-birds and other brightly coloured species; but the advent of war turned men's thoughts away from the arts of peace.

In all the considerations no biological difficulty presented itself which a thorough study of the nature and habits of the bird could not be expected to overcome; the chief problems were economic, namely, how profitably to produce the plumage in sufficient quantity to comply with trade requirements, so admirably met in the case of the ostrich. On the authority of Prof. Lefroy we learn that there are many egret farms in India, and the plumes are procured without cruelty; domestication of the same bird has also been considered in parts of Africa. With the encouragement which ornithologists could give, there is every likelihood that in the future great developments will take place in the production of domesticated plumage, procured in harmony with the highest humane sentiments and to the exclusion of plumage from the wild bird—a realisation which would be peculiarly acceptable to the trade as well as to zoologists.

Now if the Plumage Bill were passed in its present form it would close the door on all efforts of this kind, at any rate so far as importation into England is concerned. Sir Harry Johnston indicates that, as a compensation, plumage might be procured from a dozen or more kinds of our domestic birds; but surely, in these days of Empire considerations, he would not wish us to isolate ourselves in prejudice from the Dominions overseas, as well as from the products of other countries?—a result which would follow from the carrying out of his suggestion.

Nor is this necessary. A study of the situation reveals that all the reasonable requirements of the supporters of the Bill can be met, and at the same time the avenue be left open for the development within the Empire of a trade in domesticated plumage. Instead of asking for a prohibition of import of every kind of plumage (except ostrich and eider-down), let the prohibitionists and others interested in the preservation of bird-life agree upon a list of birds the protection of which is desirable from any point of view, and then have the list appended to the Bill as a schedule of prohibitions. The carrying out of the intent of the Bill on these lines would be a simple matter, and additions to, and removals from, the schedule could be made as circumstances demanded. Passed in this form, the Bill would become a real stimulus to the activities of the Royal Society for the Protection of Birds and an effective measure for the inculcation of humane principles and regard for bird-life generally.

As Prof. Lefroy has shown, the trade has no concern in avian rarities, but is prepared to work with bird-lovers in the direction of their preservation and in the discouragement of every kind of cruelty. Before the war a list of prohibited plumage had been agreed upon by the trade representatives in the leading European capitals. When the matter of bird-protection is discussed in a calm manner, with full knowledge of the facts involved, it is seen that the interests of the bird-lover and of the plumage trade are alike, and the simple modification of the Bill suggested above would meet the needs of all.

The Standard of Atomic Weights.

It is with considerable surprise, as a chemist, that I see in NATURE of April 22, p. 230, arguments as to the structure of atoms based on the deviations of the atomic weights of elements from whole numbers *on the standard* O = 16·00 The reasons for the use of this arbitrary and inconvenient standard are now matters of ancient history, and the values of Stas, which were regarded as fundamental at the time when the standard was adopted, have now been shown by many independent lines of experiment to be inexact. It is almost pathetic to observe modern experimenters who have determined equivalents by the accurate analysis of hydrogen compounds, such as hydrogen chloride, methane, hydrogen bromide, ammonia, etc., all of which are more easily obtained in a state of purity, and analysed, than oxygen compounds, compelled to multiply their results by 1·008 in order to bring them into line with the standard of O = 16·00.

A glance at the International Table of Atomic Weights will show that very few of the elements form oxygen compounds suitable for analysis, and the statement to the contrary, found in most elementary textbooks, is clearly inaccurate. A great number of equivalents, on the contrary, have been referred to Ag = 107·88. This number can be brought into ratio with oxygen only through the intermediate link of nitrogen, the atomic weight of which has been most accurately determined by the analysis of ammonia. The latter involves the ratio 1·008 to get the ratio to O = 16·00. But the atomic weight of chlorine has been most accurately determined directly to H = 1·00, and the ratio Ag : Cl is also very accurately known. From hydrogen to chlorine, from chlorine to silver, and from silver to a large number of other elements seems to be the most natural proceeding. Oxygen then comes in from the ratio H : O found by Morley, Scott, and Burt and Edgar. This is now probably one of the most accurately known atomic weights. The above is one instance only of the extraordinary branch-chain methods now necessary in order to get the experimental numbers referred to oxygen.

On the theoretical side the advantages of the hydrogen standard are self-evident. No one has ever pretended that the adoption of oxygen as the unit has any theoretical significance; the retention of the number O = 16·00 alone is sufficient to prove this. The accumulating evidence on the physical side, such as atomic numbers, the structure of atomic nuclei, the periodic law, and the like, all points unmistakably to the mass of the hydrogen atom as the natural standard. It is no longer correct to say, as is still done in elementary books, and even in other quarters, that the standard of atomic weights is a matter of indifference, and that, apart from experimental reasons, one element is as good as another. We have almost certain evidence that the hydrogen nucleus is a fundamental constituent of all atoms. Prout's hypothesis being thus reinstated, there can be no doubt as to the suitable standard of atomic weights, and Dalton's choice has had a most remarkable vindication.

When, therefore, arguments are advanced based on the standard O = 16·00, it seems time to suggest that some steps should be taken to put an end to the prevailing confusion. Physicists have never taken kindly to the oxygen standard, and there is no longer any reason why chemists should be given needless trouble. I have, in my elementary lectures, made a practice of using the hydrogen standard, and thus avoiding all the confusion in connection with vapour densities, etc., which comes in with the other system.

There is one other point which seems to me of importance. On the oxygen scale the atomic weights of a number of elements differ by about half a unit from whole numbers. It has been conjectured that these elements are mixtures of isotopes, with atomic weights which are whole numbers. But if there is anything in the theory of isotopes to justify this, it can only rest on the hydrogen nucleus, and the atomic weight of hydrogen should be taken as unity. If this is done, it is found that the suspected elements are replaced by those not at present under any clouds of suspicion. The following table will illustrate this point:

Element	Atomic Weight O = 16·00	Atomic Weight H = 1·00
Chlorine ...	... 35·45	35·18
Magnesium	... 24·32	24·14
Silicon ...	... 28·3	28·1
Zinc ...	... 65·37	64·88
Copper ...	... 63·57	63·10

It may be that there is some real physical reason for taking O = 16·00, and then supposing that, if some elements deviate from the whole number on this basis, they must be mixtures of isotopes, but this reason has so far escaped my attention.

There seems to me to be a good case for the Committee on Atomic Weights to consider whether the unit O = 16·00, adopted largely on account of the persistence of Ostwald, is any longer necessary. At best it was a temporary decision, and all the reasons which were advanced in its favour have now lost their force. I am convinced that the arguments in favour of a return to Dalton's unit are so cogent that, once they are clearly realised, they will be admitted.

Mortlakes as a Cause of River-windings.

MORTLAKE on the Thames has a place-name which not only accords with the natural history of the place, but also supplies a word which might conveniently be brought into common use to signify a process which plays an important part in the development of every river system, just as the River Meander supplies a word to signify the windings of any river. The area between Barnes and the Thames was formerly an island *in* the river (Fig. 1), formed by a

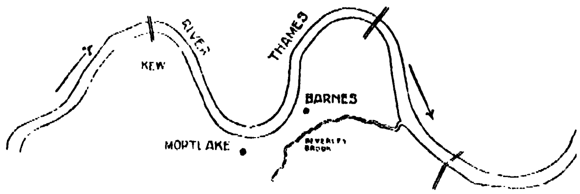

FIG. 1.

division of the stream into a northern and a southern arm reunited at the down-stream ends. The southern arm is now incomplete; the part of it remaining is included in the line of the Beverley Brook, which, having come from the south, turns to the east round a bold curve and joins the Thames. This leaves a gap between the convexity of the curve and the river at the point where it previously divided. This gap now forms the isthmus of a peninsula into which the island has been converted by the partial effacement of the southern arm of the divided river. Here Mortlake stands. It is on or near to the former line of the stream which has been in part effaced. This part has become a dead stream—a mortlake, the word "lake" having been used in the Middle English sense

as signifying a stream. Leland the Chronicler wrote that "there runneth a praty lake out of Sudeley Parke down by the Castle and runneth into Essebourne Brook at the south syde of Winchcombe." And again: "I passed over 2. or 3. small lakes betwixt Chiltinham and Gloucester and they resort to Severne." The word is still used in some places as meaning a stream; children on the Severn banks still sing of the moon as claiming to guide the ship "up the lake."

The first Lord Avebury, in writing of meanders ("Scenery of England"), mentions, as one of the results, "that the loop often remains as a dead river-channel or mortlake." Such loop-lakes are known in America as "oxbows." There is, however, a great difference. In the case of an "oxbow" the loop, formed by a lateral deviation of the river, has been entirely cut off from the main stream. A mortlake may be defined as the line of a closed part of one of the two sections of a river (previously divided so as to surround an island in the stream), the other channel remaining open and serving as a single channel for the river.

Of the two sections of a river enclosing an island, one of them at least must have a curved line. Two straight lines cannot enclose a space. If, then, the whole or a part of the stream in one of the sections be effaced, the remaining section, now forming the whole of the river, must have a more or less curved line. It must be a river-winding. The form and the length of it will, of course, depend on the shape and on the size of the former island. Thus a result of the formation of a mortlake may be one of those meanders or river-windings which are a familiar and picturesque feature in the landscape. The explanation of them has been a puzzle from classic times until the present. The subject was discussed at length by six contributors to NATURE in November and December, 1907.

I have come to the conclusion that the conversion of river-islands into areas bounded by single streams, more or less curved, is part of the ordinary course of river development. This, in my view, may be briefly stated thus: A newly exposed part of the earth's surface receives the rainfall on every square inch of it, but the water will not flow away in the form of a sheet; minute runnels form, and these will not be in straight lines parallel to each other. I cannot imagine straight "primary consequent streams" as they are sometimes depicted. Even slight obstructions would turn them aside so that they would meet and coalesce, thus forming a miniature network of streams, each of the meshes enclosing an islet. Then the water on the up-stream side of every islet will have alternative routes before it. These routes may, for a time, be equally easy, but they will not continue to be so; one of them will be preferred, and this may not be the most direct. The stream which continues may be the one which meets with the least obstruction, or it may be the one most necessary for continuance as having to receive longer or more numerous tributaries. A channel no longer needed will cease to be used; it will silt up. Then the islet will become continuous with an adjoining islet. This process being many times repeated, islands of increasing size—which may be large and, possibly, of very great extent—will result. Ultimately, they will all cease to be islands, in the absence of need for two channels. The development, in my view, is not *from* "primary streams" *into* a "complicated network" of channels, but from the complexity of a network of channels towards the simplicity of one principal stream with tributaries converging towards it. Certain it is that in a river system as we see it there is no network.

I do not wish to suggest that the formation of mortlakes is the only cause of river windings. Thirty-seven years ago I pointed out (in a paper read before a local society, and printed at the time) the influence of tributaries as one cause; and I recognise others. But the same laws govern the development of all rivers. Although Herodotus found the rivers of Egypt to be different from other rivers, I, in imagination, see the life-history of the Nile as very strikingly depicted in its present course. I have elsewhere shown ("The Lower Severn," Proceedings of the Cotteswold Naturalists' Field Club, xvi., 1909) an outline picture of a thousand miles of the Nile below Khartum compared with one of ten miles of the Severn below Gloucester. The resemblance is so close as to lead to the remark that it almost seemed as if the one figure had been drawn in ink on the second page of a sheet of paper and the other by pressing the ink before it was dry against the opposite page. The size of the two rivers and the character of the rock formations being so very different, it is at least remarkable that the course of the two should be so very much alike. In the *Times* of a recent date (March 15) is a report from Dr. Chalmers Mitchell of his view from an aeroplane in passing above the railway between Wady Halfa and Abu Hamed. He saw "huge cliff-lines submerged at intervals by desert," which suggested the "proper bed" of the Nile. It is really a relic of the time when the area, now partly enclosed by the great sickle-shaped curve of the Nile, was a huge river-island two hundred miles wide and five hundred miles long. That which Dr. Chalmers Mitchell saw was the line of the eastern arm of the Nile; it is now the line of a long mortlake.

T. S. ELLIS.

Eiffel Tower Wireless Time-Signals.

IT may interest a number of readers of NATURE to know that the Eiffel Tower is at present sending out two additional sets of "scientific" time-signals. The scientific signals are arranged as a time-vernier, gaining about one beat in fifty. They have hitherto been sent at 11.30 p.m. G.M.T., followed at 11.45, after the ordinary time-signal is concluded, by numbers which give the moment of the first and the last signal of the set, according to the standard clock of the Observatory of Paris. A comparison can thus be made with the introduction of a very small error, often not exceeding one-fiftieth of a second. These valuable signals have suffered from two awkward features: In summer time they are inconveniently late, and the purring or snoring note (*ronflée*) on which they are sent is much obscured by atmospherics when the latter are bad, so that sometimes one failed to pick up the identification breaks which occur at the end of every sixty beats.

In addition to the old series, which remain unchanged, two new series are now being sent; these are on wave-length 2600 metres and a high musical note that cannot be confused with atmospherics. Otherwise they are the same as the original —300 dots, the 60th, 120th, 180th, and 240th being suppressed. They are sent: (1) at 10.30 a.m. G.M.T., the comparison numbers giving Paris time following after completion of the 10.45 ordinary signal; and (2) at 11 p.m. G.M.T., the comparison numbers being sent after the 11.45 ordinary signal, along with those which refer to the old 11.30 signal, the two references being distinguished by the letters ML (*musicale*) and RF (*ronflée*) respectively. The new series are beautifully clear, and ought to be of great service to those who require accurate time.

R. A. SAMPSON.

Royal Observatory, Edinburgh, April 17.

Some Tests of the 100-in. Hooker Telescope.

By DR. GEORGE E. HALE, For. Mem. R.S., Director of the Mount Wilson Observatory.

THE construction of a telescope of very large aperture is necessarily an experiment the final success of which can be determined only by the results of astronomical observations. After the mechanical and optical difficulties have been overcome, there remain those disturbances of the atmosphere which are of little importance with small apertures and low magnifying powers, but become more and more serious as the diameter of the objective and the scale of the image are multiplied. Thus in undertaking the construction of a reflecting telescope of 100-in. aperture, while we had the advantage of experience with the 60-in. Mount Wilson reflector, we frankly recognised that the outcome must remain in question until the completion of tests made under customary atmospheric conditions.

As contrasted with the 60-in. reflector, the full measure of advantage attainable under *perfect* atmospheric conditions would be as follows:

	Light collecting power	Scale of focal image	Resolving power
60-in. reflector	1	1	1
100-in. „	2·8	1·7	1·7

This means that either in direct photography or in spectrographic work with a given dispersion the larger instrument should bring within range stars about one magnitude beyond the reach of the 60-in. The advantage thus gained would be important, as two illustrations, out of many that might be given, will suffice to show. Only two or three of the brightest stars can be studied with the most powerful spectrograph of the 60-in. telescope, which is not much inferior in dispersion to the instrument used by Rowland in his work on the solar spectrum. The same high dispersion, if employed with the 100-in. reflector, could be applied to several times as many stars, representing most of the principal stages of stellar evolution. At the other end of the magnitude scale, the 100-in. telescope should be able to record photographically many millions of stars too faint to be reached by the 60-in.

In the second place, the increased scale of the focal image, whether in the principal focus of the large mirror or at the Cassegrain focus, where the 100-in. telescope has an equivalent focal length of 134 ft., should separate more widely the crowded stars at the centre of globular star clusters, thus permitting them to be studied without confusion with one another; it should increase the precision of measurement in such difficult work, for example, as that involved in detecting the very small changes in the configuration of spiral nebulæ caused by their internal motions; and, to give no other illustrations, it should permit minute details, not previously photographed, to be recorded on negatives of such objects as the moon.

Finally, the increased theoretical resolving power, if realisable in practice, should permit the visual measurement of the components of very close binary stars, which cannot be separated by the smaller instrument, not merely because of the overlapping of their images during periods of poor seeing, but also because of their inherent irresolvability due to the wave-length of light itself.

In spite of the fact that most of the tests have been applied under the comparatively poor atmospheric conditions of the winter season, the early results are very satisfactory. It has become possible to include in our regular spectrographic programme stars one magnitude below those studied with the 60-in., so that the radial velocities and spectroscopic parallaxes of stars down to the tenth magnitude are being measured in large numbers by Dr. Adams and his associates. This involves a notable extension of the range of our investigations on the structure and motions of the stellar universe. Similarly, an important advance in our researches on stellar evolution has also been rendered possible, bringing to light new and curious types of stellar spectra and interesting phenomena in the spectra of variable stars at minimum brightness. The spectra of the long-period red variables of the Md class, most of which were too faint for satisfactory observation with the 60-in., are now being systematically photographed by Dr. Merrill with the Hooker telescope. One of these stars has been found to show the chief nebular lines in its spectrum, a matter of peculiar interest because of the fact that these lines have previously been observed only in nebulæ and in temporary stars. With low dispersion, the spectra of stars of the fourteenth magnitude have been photographed by Dr. Shapley with moderate exposures at the centre of globular clusters.

The preliminary results of the photography of nebulæ have also been very satisfactory, both at the principal (Newtonian) focus of the 100-in. mirror and at the 134-ft. Cassegrain focus. The photographs indicate an important advance over the 60-in. telescope, and leave no doubt that the desired increase in the precision of measurement, rendered possible by the larger scale of the images, will aid materially in the study of the internal and proper motions of spiral nebulæ. A striking feature of these negatives, as compared with those taken with the 60-in., is the increased contrast of the minute nuclei in spiral nebulæ, which are brought into greater prominence by the larger aperture. This will render available for measurement a large number of sharply defined symmetrical points.

The character of the images may be judged from the accompanying reproduction of a photograph of the moon (Fig. 1), taken by Mr. Francis G. Pease at the 134-ft. Cassegrain focus on September 15, 1919. This negative, like others obtained by Mr. Pease with the Hooker telescope, shows smaller details of structure than we have previously been able to photograph.

FIG. 1.—North central portion of the moon at last quarter. Photographed with the Hooker telescope of the Mount Wilson Observatory on September 15, 1919, by Mr. F. G. Pease. Scale: 1 in. = about 90 miles.

Perhaps the most interesting application of the 100-in. telescope hitherto made is that rendered possible by the utilisation of Michelson's interference method for the measurement of the spectroscopic binary star Capella. The method consists in completely covering the 100-in. mirror by a screen in which are two slits, which can be placed at any desired distance apart. Light coming from a point source, such as a single star at a very great distance from the earth, passes through the two slits and is brought to focus by the large mirror. A system of interference fringes may then be seen under a telescopic power of about 5000 diameters, which are sharply defined even on a night of poor seeing. If the star is single, the fringes remain visible even when the slits are separated by the full diameter of the 100-in. mirror. But if the star is a very close double, the fringes will disappear (assuming the members of the pair to be nearly equal in brightness) when the slits, set by observation at the proper position angle, are moved apart to a distance that depends upon the angular distance between the star's components.[1]

The following measures of Capella, made by Dr. Anderson, indicate the possibilities of the method:

		Position angle °	Distance ″
1919, December 30	...	148·0	0·0418
1920, February 13	...	5·0	0·0458
" " 14	...	1·0	0·0451
" " 15	...	356·4	0·0443
" March 15	...	242·0	0·0505

[1] In practice, a somewhat different technique, giving the same result with higher precision, is employed by Dr. Anderson.

When plotted, these points fall accurately on an ellipse. The method, which has been tested experimentally in the laboratory, not only allows binaries that cannot be resolved by other means to be measured with very high precision, but also permits *twice* the theoretical resolving power of the Hooker telescope to be attained in practice, even when the seeing is poor.

This application of the interferometer was suggested by Prof. Michelson many years ago and used by him in the measurement of the diameter of Jupiter's satellites at the Lick Observatory in 1891. The possibility of seeing the fringes under ordinary atmospheric conditions with the full aperture of the Hooker telescope was demonstrated by Prof. Michelson during a visit to Mount Wilson last September. The method will have many applications, and should be utilised by observers with instruments of moderate aperture who wish to resolve close doubles and to increase greatly the precision of their measures.[2]

From this record of the preliminary tests of the Hooker telescope it will be seen that in light-collecting power, in the increased scale and improved photographic definition, and in the added possibilities of optical resolution attained through the application of Michelson's method, the new instrument has not disappointed our hopes. We must now endeavour to utilise these advantages in the extension and development of our researches on stellar evolution and the structure of the universe.

[2] For an account of this method, see Michelson, "On the Application of Interference Methods to Astronomical Measurements," *Phil. Mag.*, July 1890.

Artillery Science.

By SIR GEORGE GREENHILL, F.R.S.

"THE religious attachment of the officer of artillery to the practice of his predecessors" was described by Benjamin Robins about 1740, and his attachment persisted with unimpaired devotion right up to the war. There he found himself outclassed at the outset, out-gunned and out-gunnered; the little artillery he took out was small and puny, and not of the right sort required—"pas de celle qu'il faut." Our Artillery Authority cannot be said to have understood what it spelt, the word "artillery."

On the assumption of our politicians that this country was never going to war again, an interdict had been laid on England of seven lean years; and when they were up, the lean years got an extension leading right up into the war.

A well-disciplined Army Council had been formed, obsequious to the Minister, with instructions to resist all suggestions of military progress—housed in a magnificent new palace in Whitehall, the barracks of an army of War Office clerks, provided out of a reduction of the Regular soldiers.

Temple of Victory it cannot be called. The stone slab over the portal is still blank, ready to receive the appropriate motto, with no derangement in the epitaph:

PACEM PARA BELLUM SI VIS.

The mentality of the Army Council can be glimpsed in its attitude to Flight in warfare. The Wright brothers framed on their wall the egregious answer of the Secretary in the official jargon: "I have nothing to add to my last letter to you. The War Office is not disposed to enter into relations with any manufacturers of airplanes."

This was in March, 1913, and only the next year we were running the risk of our whole Army being completely surrounded, with no airmen to scout for us. The evil name "Maubeuge" would have been written on our history as indelibly as "Jena" and "Sedan" were on others. No wonder the German squadrons could fly all over England and London with impunity, in the face of all our air defence.

The belated arrival in the war of the Tank is another similar story. Military prejudice preferred to muddle along in a stalemate of trench

warfare, at a cost of two years' delay, of intolerable waste and slaughter, before it could be persuaded to take up this new revolutionary idea. The German advance walked over our trench warfare system in the spring of 1918, and took all our guns.

Technically bold as a lion, our military soul was intellectually a very timid bird, and shuddered at any suggestion of novelty and progress. Whenever I asked an artillery officer: "What did you learn as a cadet at the Royal Military Academy?" the answer came in the invariable formula: "I learnt nothing when I was at the Shop."

The Shop! Not a workshop, except so far as the "ca' canny" slogan would carry. And yet we find this nickname, full of meaning and contemptuous, is countenanced by authority, from the Governor downward, as a surrender of all Prestige. It should be made a crime of a military nature ever to use such a derisory, contemptuous *alias*, too descriptive of the obsolete, decadent traditions of the place.

The Army List gives a whole page to the catalogue of the staff of the Royal Military Academy, Woolwich, full of official Army titles. Low down on the page a line is to be seen, and under it a list of half a dozen names, the civilian instructors who should carry out the real work of the place.

Nothing was ever so Prussian, not even in Prussia. But the line has a more sinister meaning still; it emphasises one of the important reforms of the Cardwell scheme, and excludes all those appearing under it from retiring allowance, while every Civil Service clerk is *pukka*, subsidised and covenanted, on the strength of a Civil Service examination, medical or otherwise. A sailor would compare the Academy to a boat trimming too much by the stern, with too many cocked hats in the stern sheets.

This the only source of supply of our artillery officer does not run clear; it commissions him with the brand of second class, with all the mental outlook implied of indolence and apathy.

Thinking officers among them deplore the arrangement, and are beginning to confess to their deficiency of all artillery science in the war; but, with military docility, they are afraid to say much, and formerly, before the war, would bring upon themselves the scowl of the senior officer, and the disparaging epithet of "scientific."

The old school aimed at being as close an imitation of cavalry as possible, and a stable boy was the noblest gunner of them all, prepared to carry out a gallop of a few seconds over Woolwich Common, with a little gun on wheels behind. The idea was deprecated of firing off his gun, in imitation of the practice exacted in real warfare, as likely to wear the gun out, and so provided a good excuse.

But here is a Disadvantage of Durability, especially in artillery, and most of all in its traditions. Our guns were always obsolete when they were most wanted.
